CURE: 1. Adjust the Vertical Hold (set must be turned on and operating for this adjustment).
2. If Vertical Hold doesn't fix the problem, replace the electronics module.

If the above cure doesn't solve your problem refer to the Tech Procedures to obtain the general troubleshooting procedure for this product.

Monitor II PROBLEM/CURE: Display Shrinks

Revised: 1/30/92
Security: Everyone

Monitor II PROBLEM/CURE: Display Shrinks

=====

This article last reviewed: 29 April 1988

PROBLEM DESCRIPTION: After the power is on for about 5 minutes, the display shrinks to a 3 inch (approximately) square.

WARNING: Turn off the Monitor II and unplug it whenever the case must be removed for the procedure below.

CAUSE: The regulator is loose or has become damaged from excessive heat.

CURE: Remove the regulator and replace it with a new one. Be sure to use a heat sink compound before tightening down the the regulator to the heat sink.

If the above cure doesn't solve your problem refer to the Tech Procedures to obtain the general troubleshooting procedure for this product.

Monitor II P/C: No Display, Faint Display or Fuzzy Display

=====

This article last reviewed: 29 April 1988

PROBLEM DESCRIPTION: After the Monitor II has had a chance to warm up, there is no display or faint display or fuzzy display.

WARNING: Turn off the Monitor II and unplug it whenever the case must be removed for the procedure below.

CAUSE: 1. The video connector is either not plugged in all the way or the video jack may be cracked.
2. The regulator is plugged in upside down or cracked.

CURE: 1. Plug video cable into the jack all the way and make sure the connector is not broken and fits snugly.
2. Replace regulator. Be sure to use heat sink compound before tightening it down.

If the above cure doesn't solve your problem, refer to the Tech Procedures to obtain the general troubleshooting procedure for this product.

HD20: Line voltage

Revised: 1/9/86
Security: Everyone

HD20: Line voltage

=====

Appendix A of the HD 20 Manual states that the HD 20 will work on a line voltage of 85 to 270, RMS, 47 to 64 Hz. This means that the HD 20 works without stepdown transformers, automatically switching for the power source voltage range, the 220 volt range being the most common overseas. All you need is an adapter plug for the specific locale.

LaserWriter: Slow response time

=====

This article last reviewed: 9 October 1986

The LaserWriter takes an especially long time to process the following:

1. Bit mapped fonts
2. Many font/size/style changes whether the fonts are LaserWriter fonts or bit mapped fonts
3. MacDraw with:patterns
4. Landscape orientation with:
 - a. bit mapped fonts
 - b. a clipped image that bleeds off the edge of the page
5. Images using smoothing

The LaserWriter takes a long time to process the following:

1. MacDraw with:
 - a. rotated text
 - b. clipped or cropped images
2. Landscape orientation
3. Bleeds
4. Any text over 20 points
5. Text with center, justified, or flush right
6. Text in outline or or shadow style
7. Any object scaled very tiny

8. Multiple or dashed-line styles

9. Lots of pattern shades (in PageMaker)

NOTE: PostScript errors will almost always be in this format:

%%[Error:_____; Offending Command:_____]%%

where the two blanks are the important words.

Macintosh: Maximum Clipboard Size

Revised: 9/17/87
Security: Everyone

Macintosh: Maximum Clipboard Size

=====

The Clipboard may be written to disk whenever the application requires the memory space, therefore the maximum size of the Clipboard is limited by the available disk space on the startup disk.

A more internal limit to the Clipboard occurs with the Scrap Manager, a set of routines and data types that let Macintosh applications support cutting and pasting using a specially allocated portion of RAM called the desk scrap or scrap, which is not to be confused with the Scrapbook desk accessory.

The desk scrap is initially located in a portion of RAM called the application heap. When starting up an application, the Segment Loader temporarily copies the scrap out of this heap into a portion of RAM called the stack. There is a brief moment when the scrap and a copy of the scrap both exist, the scrap in the heap and the copy in the stack; for this reason, the desk scrap cannot be bigger than half the amount of memory allocated to heap and stack.

The amount of memory allocated to heap and stack varies with each application. However, as RAM increases from 128K to 512K to 1M bytes, larger and larger amounts of RAM can be allocated to heap and stack. In a Macintosh Plus with 1Mbyte of RAM, this allocation could be as big as 800K, giving a possible Clipboard size of 400K, depending, of course, on the application.

After the copy of the scrap is in the stack, the Segment Loader reinitializes the heap, and copies the scrap back from the stack into the heap, where the Scrap Manager can use it for cutting and pasting. A handle to the scrap is stored in low memory.

An application can keep the scrap on disk, which puts a limit of available disk space on top of the limit of one-half the RAM allocated to heap and stack. To use this scrap disk file, two applications would have to have a consistent amount of RAM allocated to their heaps and stacks. The scrap of the first application could be written to disk, left on disk with warnings against dismounting the disk with the scrap file, and the second application could then read the scrap file from disk.

Notes:

..TIL01614-Macintosh-Maximum_Clipboard_Size_(TA32369).pdf

- This description idealizes the application. Keep in mind that real applications often will not handle the clipboard this way.
- Machines with 64K ROMs are limited to a maximum picture size of 32767 bytes.

Revised: 1/29/92
Security: Everyone

ImageWriter LQ General Troubleshooting (Part 3 of 3)

=====

This article last reviewed: 20 November 1987

NOTE: Detailed instructions for Take-Apart can be found in the Technical Procedures.

TESTING THE PAPER-HANDLING CHANGE SWITCH

Materials Required: Digital multimeter

Procedure

1. Turn off the printer and remove the main cover.
2. Disconnect the paper-handling change switch cable from main board connector CN18.
3. Connect the multimeter between pins 1 and 2 of the removed connector and alternately depress and release the paper-handling change switch.

When the paper release lever is depressed, the resistance should be 0 ohms. When the lever is released, the resistance should be infinite. If the resistances are not as shown, replace the paper-handling change switch.

TESTING THE PAPER FEED MOTOR

Materials Required: Digital multimeter

Procedure

1. Turn off the printer and remove the main cover.
2. Disconnect the paper feed motor cable from main board connector CN6.
3. Connect the multimeter between the pins of the removed connector listed below and verify that resistances are as shown.

Pins to measure	Resistance (Ohms)
1 and 3	20
1 and 5	20
2 and 4	20
2 and 6	20

3 and 5	40
4 and 6	40

If the resistances are not as shown, replace the paper feed motor.

TESTING THE AUTO-LOAD SOLENOID

Materials Required: Digital multimeter

Procedure

1. Turn off the printer and remove the main cover.
2. Disconnect the auto-load solenoid cable from main board connector CN8.
3. Connect the multimeter between pins 1 and 2 of the removed connector, and then between pins 2 and 3.

The resistance between pins 1 and 2 and between pins 2 and 3 should be infinite. If the resistances are not as indicated, replace the auto-load solenoid.

TESTING THE PAPER-OUT SENSOR

Materials Required: Digital multimeter

Procedure

1. Turn off the printer and remove the main cover.
2. Disconnect the paper-out sensor cable from main board connector CN9.
3. Connect the multimeter between pins 4 and 5 of the removed connector and alternately raise and release the paper-out sensor arm.

When you raise the paper-out sensor arm, the resistance should be 0 ohms. When you release the paper-out sensor arm, the resistance should be infinite. If the resistances are not as indicated, replace the paper-out sensor.

TESTING THE COVER-OPEN SENSOR

Materials Required: Digital multimeter

Procedure

1. Turn off the printer and remove the main cover.
2. Connect the multimeter between pins 1 and 13 of the removed connector and open and close the front cover.

When you close the front cover, the resistance should be 0 ohms. When you open the front cover, the resistance should be infinite. If the resistances are not as indicated, replace the control panel PCA.

TESTING THE COLOR RIBBON DETECT SWITCH

Materials Required: Digital multimeter

Procedure

1. Turn off the printer and remove the main cover.
2. Disconnect the color ribbon assembly cable from main board connector CN7.
3. Connect the multimeter between pins 7 and 8 of the removed connector and alternately depress and release the color ribbon detect switch.

When you depress the color ribbon detect switch, the resistance should be 0 ohms. When you release the switch, the resistance should be infinite. If the resistances are not as indicated, replace the color ribbon detect switch.

TESTING THE COLOR RIBBON HOME POSITION SWITCH

Materials Required: Digital multimeter

Procedure

1. Turn off the printer and remove the main cover.
2. Disconnect the color ribbon assembly cable from main board connector CN7.
3. Connect the multimeter between pins 9 and 10 of the removed connector and alternately rotate the front carrier shaft completely forward and then back slightly.

When you rotate the shaft completely toward you, closing the switch, the resistance should be 0 ohms. When you rotate the shaft slightly forward, opening the switch, the resistance should be infinite. If the resistances are not as indicated, replace the color ribbon motor assembly.

TESTING THE COLOR RIBBON MOTOR

Materials Required: Digital multimeter

Procedure

1. Turn off the printer and remove the main cover.
2. Disconnect the color ribbon assembly cable from main board connector CN7.
3. Connect the multimeter between the pins of the removed connector listed below, and verify that resistances are as shown.

Pins to measure	Resistance (Ohms)
1 and 3	70
1 and 5	70
2 and 4	70
2 and 6	70
3 and 5	140
4 and 6	140

If the resistances are not as indicated, replace the color ribbon motor assembly.

TESTING THE CONTROL PANEL SWITCHES

Materials Required: Digital multimeter

Procedure

1. Turn off the printer and remove the main cover.
2. Place the cover top down on a padded work surface.
3. Connect the multimeter between the pins of the control panel PCA connector listed below and check to see if the resistance reads 0 ohms when the corresponding control panel switch is depressed. Refer to Figure 14 to determine the location of each pin.

Switch	Check pins
Select switch	10 & 13
Print quality switch	9 & 13
Line feed switch	1 & 13
Form feed switch	12 & 13

If any switch fails to show 0 ohms when depressed, replace the control panel PCA.

EtherTalk: Ethernet-Microwave Link

Revised: 10/4/89
Security: Everyone

EtherTalk: Ethernet-Microwave Link

=====

This article last reviewed: 1 December 1987

It is possible to expand an AppleTalk LAN (using Kinetics FastPath or Apple EtherTalk interfaces) onto Ethernet and from there onto a microwave transmission system. Getting the signals to a microwave system requires some hardware: a multiplexer on each end of the microwave transmit and receive stations, connected down to the Ethernet and back onto AppleTalk with an Ethernet interface.

Another (less expensive) solution is laser technology: infrared laser systems or LED (light emitting diode) systems that can be used for short-haul communication. LED systems operate up to 2 or 3 miles, while laser systems can manage up to 40 miles. This system would work in a similar fashion to the microwave transmission system.

The physical characteristics of microwave and laser communication systems can be limiting. Based on AC technology, microwave transmitters are, in principle, AC generators with a radio frequency spectrum in the 2,000-23,000 megahertz (2-23 GHz) range. Much of this range is reserved for international and special interest communications, and leaves only sections of the possible spectrum for private use. These sections are the 2, 6, 12, 18, 19, and 23 GHz bandwidths, more than enough for most digital communication needs.

Here are some vendors of microwave components and turnkey systems (for a more complete list, contact Datapro Research Corporation):

- AT&T Network Systems
- Avantek
- Digital Microwave Corporation
- Ericsson Radio Systems
- Fujitsu America, Inc.
- Harris Farinon
- International Microwave Corporation

Asynchronous LaserWriter Driver 4.0: A Description

=====

Article Created: 15 January 1988
Article Last Reviewed: 31 October 1991
Article Last Updated: 31 October 1991

TOPIC -----

This article describes Apple's asynchronous LaserWriter driver.

DISCUSSION -----

Apple has an Asynchronous LaserWriter Driver 4.0 that allows remote locations to access a LaserWriter by modem, or access directly-connected printers by the serial port. Its built-in language (called "Asynchronous Connection Language") lets you customize connection scripts.

This driver is available from APDA, the Apple Programmers and Developers Association, and another version is available through Northern Telecom for use with their SL-1 system.

MacTerminal: How To Test Keyboard Output

=====

This article last reviewed: 4 January 1987

If you are having trouble with the keyboard output (control characters, for example) when using MacTerminal, here are some ways you might isolate the problem:

1. Use the Key Caps desk accessory to make sure your keyboard is working properly.
2. Connect your Macintosh to another Macintosh, using a serial cable.
3. Select the TTY, Local Echo, and Transparent options on the Terminal Settings window, under the Settings menu of the receiving Macintosh.

You will now be able to see if all of the ASCII values are being correctly transmitted.

ImageWriter II: Connector cables for all Apples

=====

With certain adjustments in software, the cable with order number A2C0311 can perform the same function as the cable with order number A9C0313.

But the cables themselves are different, with different pinouts, and the A2C0311 cable has about eleven intended functions while the A9C0313 cable has three. To keep the differences clear, keep this in mind:

1. The A2C0311 cable is primarily intended to connect the Apple II family to a Personal Modem.
2. The A9C0313 cable is only intended to connect the Apple II family to an ImageWriter II.

You can avoid confusing these cables by using them only for the primary intended functions specified below.

I. Apple IIe Modem-8 Cable

A. Number:

1. Order: A2C0311
2. Part: 590-0331-B

B. Configurations:

1. Primary - from Personal Modem to:
 - a. Apple II
 - b. Apple II Plus
 - c. Apple IIe
2. Secondary - from ImageWriter II or Personal Modem to:
 - a. Apple III
 - b. Macintosh XL
 - c. Lisa
3. Switching:

- a. From Apple Super Serial Card to ImageWriter II
-- SSC jumper block pointing to "TERMINAL"
- b. From Apple Super Serial Card to Personal Modem
-- SSC jumper block pointing to "MODEM"

II. Apple IIe Printer-8 Cable

A. Number:

1. Order: A9C0313
2. Part: 590-0335-A

B. Configurations:

1. From ImageWriter II to:
 - a. Apple II
 - b. Apple II Plus
 - c. Apple IIe

III. Macintosh Peripheral-8 Cable

A. Number:

1. Order: M0185
2. Part: 590-0332-B

B. Configurations:

1. From Macintosh to ImageWriter II or Personal Modem.

IV. Apple IIc Peripheral-8 Cable

A. Number:

1. Order: A2C4312
2. Part: 590-0333-B

B. Configurations:

1. From Apple IIc to ImageWriter II or Personal Modem.

LaserWriter: Using Adhesive Paper With Manual Feed

Revised: 2/12/93
Security: Everyone

LaserWriter: Using Adhesive Paper With Manual Feed

=====

Article Created: 14 January 1986

Article Change History:

02/12/93 - UPDATED
• Vendor information.

There are a several good sources for LaserWriter adhesive media:

Avery (labels, paper, transparencies)
Chart Pack (Drafting Applique Film)
Dennison (labels, paper, transparencies)
James River Corporation (labels, paper, transparencies)

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Note: The LaserWriter II's straight paper cassette path will accomodate labels. However, it is still best to use the manual feed guide on a LaserWriter or LaserWriter Plus. The two main reasons are:

1. Label stock is too thick for the paper cassette.
2. The cassette itself could separate the protective backing from the paper, which could then stick to a roller and wind around it.

Macintosh XL: Connecting it to an ImageWriter II

=====

There are two ways to connect a Macintosh XL to an ImageWriter II.

1. Use cable service part number 590-0331.
2. Use cable service part number 590-0335 (finished goods order number A9C0313) and a modem eliminator cable service part number 590-0166.

Macintosh 128K and 512K: Video Screen Specs (Discontinued)

Revised: 9/27/93
Security: Everyone

Macintosh 128K and 512K: Video Screen Specs (Discontinued)

=====

Article Created: 14 January 1986
Article Reviewed/Updated: 19 June 1992

TOPIC -----

This article contains video screen specifications for the Macintosh 128K and Macintosh 512K.

DISCUSSION -----

I. Power:

A. Input: 115 VAC plus or minus 5% (105V to 125V AC, RMS), 50/60 Hz
(frequency independent)

B. Consumption:

1. 30 Watts under normal viewing conditions
2. 60W including Video

II. Video:

A. Bandwidth: 18 MHz

B. Resolution: 512 by 342 pixels

C. Linearity: 800 TV lines at corners

D. Display capability:

1. Bit-mapped
2. Depends upon application, font, and font size
 - a. 105 columns by 27 rows in MacWrite 4.5 using Courier font at 9 points

E. CRT size: 9 inch diagonal

F. Phosphor: P4 (Aluminized)

G. Display rate: 60.15 Hz

H. Anti-glare treatment

I. External physical dimensions:

1. Width: 9.7 inches
2. Height: 13.5 inches
3. Depth: 10.9 inches
4. Weight: 16 pounds 8 ounces (including CRT)

I. CRT physical dimensions:

1. Height: 4.61 plus or minus 0.225 inches (plus or minus 11 mm)
2. Width: 6.72 plus or minus 0.155 inches (plus or minus 8 mm)
3. In production, the dimensions deviate from ideal at a maximum of 5%. Just as with any other CRT, operating temperatures will cause the image to shrink along the vertical axis. This deviation is probably not large enough to warrant adjustment of the screen.

Monitor III: Specifications (Discontinued)

=====

Monitor III

I. Power:

- A. Input: 115 VAC plus or minus 5%, 50/60 Hz (frequency independent)
- B. Consumption: 30 Watts under normal viewing conditions

II. Video:

- A. Bandwidth: 18 MHz
- B. Resolution: 900 TV lines at center
- C. Linearity: 800 TV lines at corners
- D. Display capability: 80 characters per row, 24 rows
- E. CRT size: 12 inch diagonal
- F. Phosphor: P31 (Green)
- G. External physical dimensions:
 - 1. Width: 15.5 inches
 - 2. Height: 10.5 inches
 - 3. Depth: 12.5 inches
 - 4. Weight: 8.5 kilograms (18.7 pounds)

ImageWriter LQ: It Is Upwardly Compatible With ImageWriter II

Revised: 11/22/91
Security: Everyone

ImageWriter LQ: It Is Upwardly Compatible With ImageWriter II

=====

This article last reviewed: 5 January 1987

The ImageWriter LQ is upwardly compatible with the ImageWriter II. All the functions that ImageWriter LQ shares with ImageWriter II are selected by the same commands.

The serial interface for the ImageWriter LQ is the same as for the ImageWriter II with three exceptions:

- The ImageWriter II has a baud rate range of 300, 1200, 2400, 9600. The ImageWriter LQ has a range of 1200, 2400, 9600, 19200.
- The default baud rate for the ImageWriter II is 9600. The default rate for the ImageWriter LQ is 19200.
- The ImageWriter II has a 2K input buffer. The ImageWriter LQ has a 5K input buffer (less the 32K memory option card which can be used in either printer).

Pinpoint: Version 1.1

Revised: 1/20/86
Security: Everyone

Pinpoint: Version 1.1

=====

On the Install side, five files have changed:

PINPOINT.SYSTEM - Driver restructured so as to not wipe out the interrupt vector at \$FFFE. This resolves the incompatibility with Quark Catalyst.

Driver restructured so that when searching for a disk containing sufficient space for work, if Slinky, then automatically accepted.

Install detects whether /RAM has been removed from the device table, and if so, then the bitmap is not modified. This resolves the incompatibility with MouseDesk.

Install - reads "Version 1.1 November 1, 1985".

PINPOINTPROFILE - has been changed to reflect the removal of "Cut and Paste" as an option in the Pinpoint window.

INSTALL.SYSTEM - Cosmetic change to reflect new release date and version.

1. New capability for installing Pinpoint on applications that are not in a root directory. The logic is as follows:

First, all devices are searched for the desired startup program (i.e. APLWORKS.SYSTEM). If it is not located on any disk drive in a root directory, a dialog box appears. It requests for the user to insert the correct disk or press Open-Apple-P to specify explicitly the pathname of the application. If the user presses Open-Apple-P, then he is prompted for the pathname. For instance, if you Appleworks is set up on your profile disk under the APPLEWORKS path, then you would type /PROFILE/APPLEWORKS. The program would then enhance /PROFILE/APPLEWORKS/APLWORKS.SYSTEM.

BIG IMPORTANT NOTE: Quark Catalyst renames the AppleWorks startup filename to "APPLWORKS." from "APLWORKS.SYSTEM". Pinpoint searches for "APLWORKS.SYSTEM", and will not locate the renamed file. If the user is using Quark Catalyst, they must install to the 5.25" floppy diskette.

2. A warning message is now issued if you "Quit" the installation program after having changed some parameters and not installing Pinpoint on any program.

CATALYSTDESKTOP - Cosmetic change to reflect new release number and date. In addition, cut-and-paste references have been removed.

IMAGEWRITER.0 - Imagewriter print driver was changed so as to suppress the "Z" that appeared in GraphMerge preceeding the second graphic image on an Apple IIc.

SCRIBE.0 - Same as above for Scribe.

FLIP SIDE - Several Accessory files have been changed.

CUTANDPASTE.PP - has been removed from version 1.1.

GRAPHMERGE.PP -

Graphmerge now works better with extra RAM and version 1.3 of AppleWorks. Version 1.2 of AppleWorks does not recognize the Memory, so therefore it left it alone. It now recognizes it, and uses it as part of its desktop. This slows down the performance of GraphMerge because it cannot expand. In version 1.0 of Pinpoint, work files were created and rendered unusable because of the memory usage of 1.3. The temporary work files are no longer created. In either case the user cannot really tell that there is a difference.

In addition, when going to Open a document with a memory card intact, the /RAM drive always appeared first. It will now bypass that drive.

DIALER - Now provides a broader support for modem dialing. This is done by broader serial card support.

COMM.PP - Communications has been improved to resolve some problems in release 1.0

1. There is now XON/XOFF support in PLAY mode, so that the user can send information to CompuServe, MCI, etc., correctly.

2. The code has been restructured so that it is more organized and expandable in the future.

3. There is a broader support for modems and interface cards.

4. This version will run more reliably on an enhanced IIc (that is "c" not "e"). The machine check has been improved.

CALENDAR.PP - The calendar was improved to handle the "Disk Full" condition appropriately.

1. Previously, if the disk full condition arose, an invalid pointer was left

in the file. This leads to perpetual "Disk=Error" condition when the disk does not even spin.

Pinpoint: Version 1.2

Revised: 1/20/86
Security: Everyone

Pinpoint: Version 1.2

=====

This release of Pinpoint primarily broadens our Modem support base. It now supports the MicroModem IIe and Zoom Telephonics internal modems in the touch tone dialing mode. Please note that version 1.2 does not support the Novation modems as originally planned. The communication package has been, once again, improved dramatically.

Version 1.2 also corrects some printing problems in GraphMerge related to headers/footers and proportional font selections.

Version 1.2 includes a brief BASIC program that can lengthen the phone dialer delay (for rotary dialing) or change the Imagewriter reset (in that Imagewriter 2 does not reset).

A more reliable check for "Something in the slot" has been added for printing. This way the Typewriter will not crash if nothing is installed in the printer slot.

Communications/Dialer changes

The communications package has been enhanced. The XON/XOFF problem described in technical note TN-008 has been corrected. Premature disconnect when pulse dialing has been corrected (TN-014). Possible over-writing of the phone directory when recording has been corrected. Control characters are now filtered out in communications, with the exception of Control-Q.

In addition, the auto-answer mode has been corrected. Previously, a phone call had to be made within about 30 seconds, or it would have given up in despair. In addition, manual dialing can be done for those modems without auto-dialing capability.

Hidden within Version 1.2 is also a whole world of capability that will be addresses in a supplementary disk. This allows the user to define a handshake character, remap characters incoming and outgoing, etc.

Specific Modem Support:

Version 1.0/1.1 worked with an Apple Super Serial card and various external modems, such as:

Apple 300/1200 Baud
All Hayes external
Prometheus 1200 external
Prometheus 300c external
Volksmodem 12 external
Popcom X100

Now, release 1.2 also incorporates:

Hayes Micromodem IIe internal (tone dialing only)
Zoom Modem IIe (tone dialing only)

In addition, Version 1.2 broadens the interface card support beyond the Super Serial card to include:

A.S.T Multi-I/O card
Prometheus Versa Card
C.C.S. I/O card
A.I.O. I/O card
Apple Serial card

The ZAP program

The ZAP program is a very simple BASIC program that allows the user to change two things: his timing delay when dialing via a rotary dial, and the reset of his Imagewriter printer.

The reason for changing the delay for rotary dialing is that rotary dialing takes significantly longer than pulse, and the phone dialer may terminate and go back to the application before even finishing dialing. The user can lengthen this time period.

12345678901234567890123456789012345678901234567890123456789012345678
The reason for the Imagewriter reset disable is that we reset the Imagewriter to its startup values when we are done printing. This change will prohibit the resetting of the printer. This allows people with Imagewriter II's to maintain their near-letter-quality setting throughout.

In order to run the Zap program, the person should startup their copy of Pinpoint Install disk, and select BASIC. Once basic is selected, the user is placed in an immediate command mode. The user should type "-ZAP" followed by return. The user then chooses a menu selection item as shown below:

-ZAP

0. Quit this program
1. Run the Installation program
2. Modify ImageWriter driver for no reset
3. Change Dialer delay

TYPE CHOICE, THEN <RETURN>

Once the user has carried out their zap, they must then re-install Pinpoint on their program.

Pinpoint: Auto-copy capability

Revised: 1/20/86
Security: Everyone

Pinpoint: Auto-copy capability

=====

Pinpoint automatically copies desktop accessories from the disk to the RAM drive if:

- (a) your Apple is equipped with the Apple Memory Card, or
- (b) your machine is equipped with the Applied Engineering Z-RAM or RamWorks, or Checkmate MultiRam, your memory is partitioned such that a RAM drive exists while AppleWorks is running, and Pinpoint has been enhanced so as to treat the third party cards as equivalents to the Apple Memory Cards.

If you do not wish certain accessories to be copied to the RAM drive at startup, a "patch" can be applied to a file called "PINPOINTPROFILE" on the installation side of the Pinpoint disk.

The file "PINPOINTPROFILE" contains a description of each desktop accessory installed. This description entails the Accessory name (that appears in the Pop-Up window), the ProDOS system file name, the memory requirements for each accessory, as well as modem and printer parameters. In addition, a flag is set for each accessory that should be copied to the RAM drive at startup.

The file "PINPOINTPROFILE" is 768 bytes long. The last 16 bytes in the file are set to "1" or "0". A "1" means that the accessory should be copied to the RAM drive at startup if a RAM drive is available, a "0" means no. The order corresponds to the order that the accessories appear in the pop-up window.

Assume that we load the "PINPOINTPROFILE" file in memory:

```
BLOAD PINPOINTPROFILE,A$1000  
PRINT PEEK(4848)
```

A "1" would print. This means that the Appointment Calendar accessory (CALENDAR.PP) should be copied to the Ram drive at startup. If this was set to "0", then it would not be.

Once the changes have been made to "PINPOINTPROFILE", the file should be save

back to disk via:

```
12345678901234567890123456789012345678901234567890123456789012345678
BSAVE PINPOINTPROFILE,A$1000,L$300
```

At that point, you can re-install Pinpoint on AppleWorks with the associated changes.

OPTIONALLY, the Ram Enhancement Kit WILL allow you to selectively choose the accessories and ProDOS files that you want to go into RAM.

Pinpoint: RAM drive tech notes

Revised: 1/20/86
Security: Everyone

Pinpoint: RAM drive tech notes

=====

If your machine is equipped with the Applied Engineering RamWorks Card, and you are using version 4.3 (or greater) of the Desktop Expander as well as Version 3.3 (or greater) of the Ramdrive software, you can patch Pinpoint so that it automatically copies your desktop accessories to the RamWorks card. This makes the accessories lightning fast.

First, you must run the "Partition" program on the Ramdrive so as to divide memory between AppleWorks and the Ram drive. Pinpoint can use about 192K on the Ram drive if available

Once you have set up your ProDrive and AppleWorks to run with partitioned memory, install Pinpoint on the patched AppleWorks disk.

Next, set up a startup disk with BASIC.SYSTEM on it, as well as PRODRIVE, APLWORKS.SYSTEM, and any other associated files.

The "Startup" program for basic should be as follows:

```
5 PRINT CHR$(4);"PREFIX /APPLEWORKS"
10 PRINT CHR$(4);"BLOAD PRODRIVE"
20 CALL 8192
30 PRINT CHR$(4);"BLOAD APLWORKS.SYSTEM,TSYS,A$2000"
40 FOR I=1 TO 8: READ X: POKE 10367+I,X: NEXT
50 CALL 8192
60 DATA 201,48,240,2,56,96,24,96
```

Pinpoint offers the Ram Enhancement Kit. It is more elaborate, and automates this process quite a bit.

Pinpoint: BASIC Programming Considerations

Revised: 1/20/86
Security: Everyone

Pinpoint: BASIC Programming Considerations

=====

Memory Usage

When Pinpoint is installed to operate in conjunction with the ProDOS interpreter BASIC.SYSTEM, it occupies some memory space on the \$300 page. It requires the memory space from \$300 thru \$3BA. This area is not used at all by BASIC, but is often used by small machine language programs. If a small machine language program is loaded here, you will lose control of your machine keyboard.

In addition, a 16K portion of the /RAM drive is reserved for Pinpoint, reducing the block count available on the RAM drive by 32 blocks. The Pinpoint Dispatcher is stored away in the upper 16K of the Extended memory bank.

Key trapping

If your program uses the standard BASIC character reading capability (i.e. Input, Get), then Pinpoint can trap the Solid-Apple-P key. If you call a machine language routine for keyboard input, it will not be intercepted by Pinpoint. If you wish to check the \$C000 strobe in your machine language program, you can call \$32D. It will return the standard result of an LDA \$C000 providing that a Solid-Apple-P has not been hit.

Invoking Pinpoint directly from BASIC

If you wish, you can invoke Pinpoint directly from your program. This would allow you to re-assign the Pinpoint key. Simply CALL 883 from BASIC (JSR \$373 from Machine Language). This will cause the Pinpoint Accessory Menu to appear.

Pinpoint 1.0: No XOFF recognition in Play Mode

Revised: 1/20/86
Security: Everyone

Pinpoint 1.0: No XOFF recognition in Play Mode

=====

XON/XOFF

Symptom:

When Pinpoint is in PLAY mode, it reads a file contents and transmits it. Should the reciever issue an XOFF during the process, Pinpoint continues to transmit data. This will result in lost information for the reciever. A stream of ^S (XOFF) characters may appear on the screen.

User Action:

The user is stuck here. He should press the ESC key to pull down the FILE menu, and select "Play File Done".

A Note:

Should Pinpoint be a recording terminal, then an 8K recieve buffer is used to store incoming characters. Once the 8K buffer is full, an XOFF character is sent to the source encouraging them to suspend transmission of data. Pinpoint then flushes the 8K buffer to disk and issues an XON to resume recording.

FIXES:

There is no fix for this that can be applied by the customer. Version 1.1 will remedy this problem by recognizing XOFF from the sending terminal.

Once an XOFF signal has been sent by the host machine, then Pinpoint will hover around waiting for an XON (or an ESCAPE key pressed by the user).

LaserWriter: Using non-AppleTalk connectors with AppleTalk

Revised: 4/9/91
Security: Everyone

LaserWriter: Using non-AppleTalk connectors with AppleTalk

=====

With the Macintosh Plus, use the Macintosh Peripheral Cable, M-0185, and connect the 9-Pin end of the M-0185 to the LaserWriter and the Mini-8 end to the Macintosh Plus printer port.

To connect a single Macintosh or Macintosh XL to a LaserWriter without using the AppleTalk connector modules, construct a new cable using the following pinouts:

Macintosh Plus Mini-Circular 8	Macintosh DB-9	Macintosh XL DB-25	Signal	LaserWriter DB-9	Signal
4	3	1	GND	3	GND
6	4	20	TXD+	8	RXD+
3	5	2	TXD-	9	RXD-
8	8	9	RXD+	4	TXD+
5	9	3	RXD-	5	TXD-

Set the LaserWriter's mode switch for "AppleTalk", use the control panel to "Connect" AppleTalk, and use "Chooser" to select the LaserWriter.

CAUTION! To avoid FCC Class B signal violation, this cable should be fully shielded, as the data is at a very high rate and is not attenuated by the connection boxes normally used in AppleTalk.

Pinpoint: RAM CARDS, Compatibility

Revised: 1/20/86
Security: Everyone

Pinpoint: RAM CARDS, Compatibility

=====

Pinpoint, AppleWorks and the Apple Extended Memory Card

Pinpoint will automatically recognize an Apple Extended Memory card installed in an Apple IIe. It will use this memory to speed up access to your desktop accessories. When you program starts up, the desktop accessories will be automatically copied over to the corresponding RAM drive on the expanded memory card. Access to the accessories will be near instantaneous.

It is advisable to start up your AppleWorks program with your accessory disk in the second drive. This way the desktop accessories can be automatically copied to the memory card.

Pinpoint can be modified to prevent certain (or all) desktop accessories from being copied to the RAM disk provided by the memory card. This may be applicable, for instance, if you don't have a modem, and wish not to have the communications package installed in memory. This modification is available from Pinpoint Publishing for a cost of \$8.00, and can be ordered directly either by phone or mail. The product name is "Pinpoint RAM Enhancement Kit".

Pinpoint, AppleWorks and RamWorks/Z-Ram

If you are using the RamWorks or Z-Ram products from Applied Engineering, you will need version 4.3 (or greater) of the Super AppleWorks Desktop Expander. If you are using an earlier version, contact Applied Engineering for the most recent copy. Pinpoint will not run with earlier versions of the AE desktop expander.

Pinpoint can take advantage of the extra memory contained on your memory card if a portion is configured as a RAM drive. This will require the ProDrive software from Applied Engineering. Be sure to use the ProDOS version. By having the RAM drive available while running AppleWorks, Pinpoint will use it for creating necessary temporary files. It will provide access to your desktop accessories much more quickly.

In addition, there is a modification that you can install on Pinpoint so that it automatically copies the desktop accessories to the RAM drive when you start your AppleWorks up. This provides near-instant access to your accessories. In order to use this option with RamWorks or Z-Ram, it is recommended that your machine contains at least 512K. This modification is available from Pinpoint Publishing for a cost of \$8.00, and can be ordered either by phone or Mail. The product name is "Pinpoint RAM Enhancement Kit".

Optionally, you could use the RAMDrive software Ver. 3.3+ to create the RAM drive locking out the appropriate banks for AppleWorks. Bank 0 should be locked out for use by Pinpoint. It is advisable to leave about 3 banks of memory available for use by the Ram drive. You could then use the "COPY.FILES" program provided on the ProDrive disk to copy all or some of the following files:

CALENDAR.PP	- Appointment Calendar
CALCULATOR.PP	- Calculator
COMM.PP	- Communications Window
GRAPHMERGE.PP	- GraphMerge
NOTEPAD.PP	- Notepad
QUICKLABEL.PP	- QuickLabel
TYPEWRITER.PP	- Typewriter

Pinpoint and Checkmate Technologies Board

If you are using the Checkmate MultiRam IIe, you will need version 4.0 (or greater) of the AppleWorks Memory Expander. If you are using an earlier version, contact Checkmate Technologies for the most recent copy. Pinpoint will not run with earlier versions of the memory expander.

Pinpoint can take advantage of the extra memory contained on your memory card if a portion is configured as a RAM drive. This will require the Utility software found on the flip side of the MultiRam disk. Be sure to use the ProDOS Ram drive. By having the RAM drive available while running AppleWorks, Pinpoint will use it for creating necessary temporary files. It will provide access to your desktop accessories much more quickly.

In addition, there is a modification that you can install on Pinpoint so that it automatically copies the desktop accessories to the RAM drive when you start your AppleWorks up. This provides near-instant access to your accessories. In order to use this option with MultiRam, it is recommended that your machine contains at least 512K. This modification is available from Pinpoint Publishing for a cost of \$8.00, and can be ordered either by phone or Mail. The product name is "Pinpoint RAM Enhancement Kit".

Optionally, you could set up the RAM drive yourself, and use the FILER program to copy the following programs to your RAM drive:

CALENDAR.PP	- Appointment Calendar
CALCULATOR.PP	- Calculator
COMM.PP	- Communications Window

GRAPHMERGE.PP	- GraphMerge
NOTEPAD.PP	- Notepad
QUICKLABEL.PP	- QuickLabel
TYPEWRITER.PP	- Typewriter

Pinpoint 1.0/AppleWorks/Catalyst 3.0 Incompatibility

Revised: 1/20/86
Security: Everyone

Pinpoint 1.0/AppleWorks/Catalyst 3.0 Incompatibility

=====

There is a problem using Pinpoint 1.0 installed on AppleWorks run from Catalyst 3.0.

Symptom:

User runs AppleWorks, uses Pinpoint accessories, and everything appears Rosy. When he exits AppleWorks, to return to Catalyst, the Catalyst desktop appears (less any icons), and then the machine hangs. Now since Pinpoint was not being used, and he was in AppleWorks, the user may not think of it as a Pinpoint problem. In addition, since he has already exited AppleWorks, the user will probably perceive it as a Catalyst problem.

User Response:

He must restart the machine via the Control Reset keys.

Resolution:

Version 1.1 has corrected this problem.

Pinpoint 1.0/AppleWorks/MouseDesk Incompatibility

=====

There is a problem using Pinpoint installed on AppleWorks run from MouseDesk.

Symptom:

MouseDesk removes the /RAM drive and does not install it when AppleWorks gains control. Pinpoint attempts to access the RAM drive and crashes to the monitor before AppleWorks even runs.

User Response:

The user should either

(a) send back the Pinpoint disk to receive a more recent version (this problem has been corrected in Version 1.1).

(b) the user can apply a minor patch to Pinpoint and re-install to AppleWorks.

The patch procedure (Version 1.0 only) is as follows:

1. Backup your Pinpoint disks.
2. Startup your Apple with ProDOS BASIC.
3. Place a copy of the Pinpoint Installation disk in drive 1, slot 6.
4. Type "PREFIX,S6" (less the quotes, of course) terminate each line with the Return key.
5. Type "BLOAD PINPOINT.SYSTEM,TSYS,A\$2000"
6. Type "POKE 9203,96"
7. Type "BSAVE PINPOINT.SYSTEM,TSYS,A\$2000,L15104"

Resolution:

Version 1.1 has corrected this problem.

Pinpoint 1.0: Rotary Dialing

Revised: 1/20/86
Security: Everyone

Pinpoint 1.0: Rotary Dialing

=====

Symptom:

The user is attempting to dial a number using a Rotary option, as opposed to the Pulse option. The dialing is not completed.

Solution:

If possible, have the user to switch to pulse dialing in the installation options, and re-install.

If not possible, they have two options. First, have them send back their disk to upgrade to 1.1. This will be corrected in 1.1.

In addition, if they wish to apply an interim solution to version 1.0, the following poke will work:

1. Startup a copy of the Pinpoint installation disk. Select Basic.
2. Type the Following:

```
BLOAD PINPOINT.SYSTEM,TSYS,A$2000
POKE 20124,128          (this number can be up to 255)
BSAVE PINPOINT.SYSTEM,TSYS,A$2000,L15104
```

3. Re-install Pinpoint on their AppleWorks disk.
12345678901234567890123456789012345678901234567890123456789012345678
The "128" above is a delay count before resetting the modem. It's default value is 56. It's maximum value is 255.

Pinpoint 1.0: Dialing Long Distance W/Out Equal Access

=====

Symptom:

Certain communication systems (not Bell, therefore a very minor market share) do not tolerate a "1" preceeding a long distance call. This is typically the case where Equal Access has not yet been supported in the state.

A superfluous "1" preceeds the long distance call. The incorrect number is dialed.

Resolution:

The user can patch Pinpoint to bypass the "1" from being generated. This patch will vary in release 1.1. The patch below is only applicable to version 1.0.

The user should startup the Pinpoint installation disk and select Basic from the menu.

He should then type: (Version 1.0 only)

```
BLOAD PINPOINT.SYSTEM,TSYS,A$2000
POKE 19550,32
BSAVE PINPOINT.SYSTEM,TSYS,A$2000,115104
```

The user should then Re-Install Pinpoint on his AppleWorks.

Pinpoint GraphMerge: Problems printing footer messages, page #s

=====

Problem:

GraphMerge would incorrectly handle page footers in an AppleWorks document. In reality, the footer was handled correctly, but the following line of text from the document would disappear from the document. In addition, the page numbering scheme would be incorrect.

Solution:

1. Have the user send back the disk for version 1.2 or greater, the problem has been resolved.
2. Have the user avoid page numbers and footer messages in the interim.

Pinpoint: Using Serial-To-Parallel Translators on IIC

Revised: 1/20/86
Security: Everyone

Pinpoint: Using Serial-To-Parallel Translators on IIC

=====

Sympton:

The user has an Apple IIC and a parallel printer (i.e. Epson or Okidata) hooked up by way of a translator box. The user attempts to print and gets the message "No printer Connected".

Problem:

Pinpoint (version 1.0/1.1/1.2) will not properly handle a parallel printer hooked up to a serial interface by way of a black box. This is because if a parallel printer is selected, it is assumed to be connected to a parallel interface, not a serial interface. The two interfaces handle handshaking differently.

Solution:

Until we come up with a more elaborate scheme for installing printers and interfaces, the pokes below will work. The user should start up the Pinpoint install disk, Select BASIC, and type the following commands. He should then re-install on AppleWorks.

Pokes for versions 1.0/1.1

```
BLOAD PINPOINT.SYSTEM,A$2000,TSYS
POKE 20545,128
POKE 20546,5
BSAVE PINPOINT.SYSTEM,A$2000,TSYS,L15104
```

Then have the customer re-install on AppleWorks.

Poke for version 1.2

```
BLOAD PINPOINT.SYSTEM,A$2000,TSYS
POKE 20552,128
POKE 20553,5
```

BSAVE PINPOINT.SYSTEM,A\$2000,TSYS,L13568

And re-install.

Apple IIC Upgraded Motherboards: Diagnostics Error (9/95)

=====

Article Created: 20 January 1985
Article Reviewed/Updated: 19 September 1995

TOPIC -----

After an exchange of an upgraded Apple IIC motherboard, running old versions of the Apple IIC diagnostics results in an error condition, most frequently error code number 299.

DISCUSSION -----

The older versions of the diagnostics will not work properly with the upgraded motherboards. Use the most current version of Apple IIC diagnostics (at least Rev. C).

Revised: 1/20/85
Security: Everyone

Apple Writer WPL Manual: Erratum

=====

There is an error on page 110 of the manual for Apple Writer DOS 3.3 disk that runs on the Apple IIe only.

The instructions on running AUTOLETTER2 include the line

```
DO AUTOLETTER2,D1
```

but the appropriate file on the Apple Writer disk is named

```
WPL.AUTOLETTER2.
```

Revise the line in the program to read:

```
DO WPL.AUTOLETTER2,D1 (or the number of the appropriate disk drive)
```

The Apple Writer ProDOS disk doesn't have an AUTOLETTER2 program. Change the program or rename AUTOLETTER1 as appropriate

Apple IIc External Drive : PR#7 Can't Boot

Revised: 11/10/88
Security: Everyone

Apple IIc External Drive : PR#7 Can't Boot

=====

Article Created: 23 January 1986
Article Last Reviewed: 17 July 1992
Article Last Updated:

PROBLEM DESCRIPTION: Attempt to boot external disk drive PR#7.
No boot action and the words "AppleTalk Offline" appear at the
bottom of the screen.

CAUSE: You may have a logic board which has ROMs compatible with the
UniDisk 3.5 installed. Using PR#7 to boot the external drive is a feature
which was discontinued in these ROMs to make room for other new
features.

CURE: If you are using a UniDisk 3.5 use PR#5 instead of PR#7. If
you are using any other drive, you can not boot from the external
drive.

DWP Prob/Cure: On Pwr Up, Carriage Jams to Side/Printwheel Spins

Revised: 7/22/88
Security: Everyone

DWP Prob/Cure: On Pwr Up, Carriage Jams to Side/Printwheel Spins

=====

This article last reviewed: 20 July 1988

PROBLEM DESCRIPTION: When the DWP is turned on, the printwheel spins at high speeds or the carriage jams to the right or left side of the printer.

CAUSE:

1. The drive circuits in the printwheel servo or the carriage servo have blown.
2. If it's an old logic PCB, one of the buses may have broken connection with the PCB.

There are 4 revs of DWP Main Logic PCBs (A1,A2, B, and C). The older rev PCBs (A1, A2, and B), have very fragile busses which are light colored strips mounted lengthwise along the component side of the PCB. If the PCB is flexed lengthwise (even slightly), pins on this bus will break from contact with the PCB. Most often this break is invisible to casual inspection.

One of the most common problems a break on the bus can cause is to prevent a power supply voltage from getting to the encoder PCB. This will cause the encoder PCB to output an error voltage to the servo loop. If it's the printwheel servo loop the printwheel will spin in one direction. If it's the carriage servo, the carriage will slam to one side.

Since it is so easy to break these buses, many well intentioned techs have accidentally damaged PCBs before installing them causing the same symptoms to occur after replacement as were there before.

CURE: "Carefully" replace the logic PCB.

If the above cure doesn't fix the problem, refer to the Tech Procedures to obtain the general troubleshooting for this product.

AppleTalk: Troubleshooting The Network

Revised: 11/2/88
Security: Everyone

AppleTalk: Troubleshooting The Network

=====

This article last reviewed: 6 January 1988

Even with a network as easy to use as AppleTalk, problems can still be tricky (especially as networks grow larger). Here are a few things you can do to isolate, and deal with, most of the problems that occur before calling your local Technical Support Engineer.

AppleTalk problems usually have one of three causes:

- 1) Incompatible System and Finder versions
- 2) Loose connections
- 3) Circular or other improper connection of the network

Making sure your Macintosh users are running from the most current versions of the System and Finder is always important, but when they are networked, it's critical. Go to each Macintosh and use the Get Info command to check the version numbers of both. People who don't use hard disks must update all of their disks containing System Folders. The next thing to check is the integrity of the network connections. If the network includes a LaserWriter or AppleTalk ImageWriter printer, a simple way to isolate the problem is to open the Chooser desk accessory on each Macintosh. If the networked printer shows up in the Chooser, the connection between that Macintosh and the printer is good. By checking systems as you move away from the networked printer, you can discover where the connection is broken and isolate the problem. Remember, AppleTalk must be connected to the printer port.

Diagramming the network is a good idea even before you have problems, but it's also an excellent way of discovering circular or other improper connections. AppleTalk is a "bus" topology network, which simply means that the network should have only two end points and no circular connections. An end point (or terminator) is the last AppleTalk connector on either end of the network. The two terminators should be the only

connections on the network that have only one cable attached.

Because most problems with AppleTalk are related to the three causes mentioned, these troubleshooting tips should help you most of the time. When they don't, it's time to call your local Technical Support Engineer.

ImageWriter II: Paper Feed and Detection Problems(1 of 2)

Revised: 1/30/92
Security: Everyone

ImageWriter II: Paper Feed and Detection Problems(1 of 2)

=====

This article last reviewed: 10 March 1988

#1: ImageWriter II Prob/Cure: Paper Out is Not Detected

PROBLEM DESCRIPTION: The printer indicates that there is paper in the printer even when there isn't any.

NOTE: An ohm-meter will be needed for the following procedure.

CAUSES:

A: Mechanical paper out sensor may be malfunctioning.

CURE: To test the sensor's switch, perform the steps below:

1. Turn the printer off and then on to eliminate any possibility of a software problem. Then recheck for the problem.
2. Follow the procedure in the Tech Procedures to remove the Top Cover to expose the logic PCB.
3. Locate and remove CN9 (a two wire connector on the left side of the PCB as you are facing the front of the printer).
4. Insert paper into the printer and measure the resistance between the two pins on CN9 (the connector that you removed from the PCB). The resistance should be infinite with the paper inserted
5. Continue to measure the resistance between the two pins as you remove the paper. The resistance should be between 0 and 50 ohms with the paper removed.
6. If both resistance checks were OK, the paper out sensor switch is "not" faulty. Replace the logic PCB.

B: Optical paper put sensor may be malfunctioning.

1. CAUSE: Platen may be dirty or covered with ink. The ink build up makes the platen surface reflective which causes platen surface to reflect the light from the optical paper sensor.

CURE #1: Clean the platen surface with a typewriter platen cleaner such as FEDRON (c).

CURE #2: Replace the platen.

- 2: CAUSE: Faulty optical paper out sensor. This might only be noticed when a sheetfeeder is attached to the printer. The printer will work except when the sheetfeeder is added, then the printer won't feed the paper from the sheetfeeder.

CURE: Replace the optical paper out sensor assembly.

- 3: CAUSE: Bad logic board.

CURE: Replace the logic board.

#2: IW I/II Prob/Cure: Error Lamp Blinks When There Are No Jams

NOTE: An ohm-meter will be needed for this procedure.

PROBLEM DESCRIPTION: Cover is correctly installed and there appear to be no paper or print mechanism jams.

CAUSE/s: 1. If the printer is an ImageWriter II, the option card DIP switch may be improperly set or the magnet on the cover may have fallen off.

2. If the printer is an ImageWriter I or II, the magnet on the cover may not be activating the magnetic "cover on" sensor switch.

CURE/s:

ImageWriter II 1. Check the printer to see if a 32K buffer card or an AppleTalk interface card is installed. If either is installed, make sure that option card DIP switch SW2-4 is closed. If neither card is installed, make sure that option card DIP switch SW2-4 is open.

2. Remove the operation panel and confirm that the magnet is properly installed. If the magnet is OK, find the two terminals for the magnetic switch on the non-component side of the PCB. Position the magnet on the paper cover next to the magnetic switch on the component side of the PCB while checking for continuity between the two terminals as the magnet contacts the switch the switch should close and you should read a short. If the switch stays open, it is defective so replace the operation panel.

ImageWriter I - Replace the magnetic reed switch then recheck for the problem. If the problem is fixed, that means that the magnetic "cover on" sensor switch was malfunctioning such that the magnet on the cover could not activate it

#3: ImageWriter II Prob/Cure: Tractor Feed Paper Jams

PROBLEM DESCRIPTION: Paper jams in the ImageWriter II when using tractor feed paper.

CURE/s:

1. Turn the power on so that the head centers prior to feeding the paper.
2. If using tractor feed, DON'T switch the feed setting to friction feed. The platen has overdrive, which maintains tension on the paper by moving the platen faster than the paper so if the paper is still on the tractor feed pins, it would be ripped off.
3. If using tractor feed, check that the paper is feeding in properly with the tractor. It could be catching on the back of the paper guide.
4. If using friction feed and the paper scrunches, insert a new clean sheet before using friction feed.
5. Make sure that drive select is in the proper position. Don't flip it back and forth.
6. If none of the above solves the problem, replace the logic PCB.

#4: ImageWriter II P/C: Pin Feed Paper Jams (scrunches)

PROBLEM DESCRIPTION: Paper is jamming when using pin feed.

CAUSE: Paper is 15-pound or lighter or printer has a failed logic PCB.

CURE: Check the following:

1. Be sure the paper is feeding properly and is not catching on the back of the paper guide.
2. Make sure the switch is positioned to "Tractor Feed."
3. If your are using 15 pound paper, try a different weight paper (heavier than what you are using).
4. Replace the logic PCB.

If this cure does not resolve the problem, go to "ImageWriter II Problem/Cure-Paper Feed and Detection Problems(2 of 2)"

ImageWriter II Problem/Cure: Prints Over Perforation

Revised: 11/10/88
Security: Everyone

ImageWriter II Problem/Cure: Prints Over Perforation

=====

This article last reviewed: 29 April 1988

PROBLEM DESCRIPTION: When printing to the ImageWriter II, the document seems to go to the next page, prints a few lines, then leaves about 3/4 to 5/8 inch of blank lines and then starts printing again. This condition gets worse as you print until the printer starts to print over the page perforation.

CAUSE: Switch 1-5 may be in the CLOSED position. This switch activates the PERFORATION SKIP function.

CURE: Turn the printer off. Put switch 1-5 in the OPEN position. Turn the printer back on.

Hard Disk 20: Boot From HD20 Locks Up HD20 and Macintosh

Revised: 11/10/88
Security: Everyone

Hard Disk 20: Boot From HD20 Locks Up HD20 and Macintosh

=====

This article last reviewed: 20 July 1988

PROBLEM DESCRIPTION: When trying to boot from a non-SCSI Hard Disk 20, the system fails to complete its boot. The Macintosh ejects the Sony disk, and both the hard disk and Macintosh locks-up.

CAUSE: The Finder file on the hard disk may be corrupted.

CURE: Try each of the following until the problem is fixed.

1. Replace the HD-20's Finder File:
 - a) Turn on the HD 20. Switch off Macintosh, insert Hard Disk 20 Startup Disk in the internal disk drive, and switch the Macintosh on again.
 - b) When you see the "Welcome to Macintosh" prompt, hold down the mouse button until the Finder is completely displayed (the wristwatch turns into a pointer).
 - c) The Hard Disk 20 Startup disk is now the current startup disk. Display the contents of the System Folder on the HD Start-Up disk. Select the Finder file and go to the "File" option on the menu bar to "Get Info" for revision information on the Finder file. It should be revision 5.0 or better
 - d) Display the contents of the System Folder on the Hard Disk 20 to ensure that the HD 20's Finder and System files are located there. If they aren't, find them on the HD 20 and move them into the HD 20's System Folder.
 - e) If the HD 20 Start-Up disk's Finder file was an acceptable revision, drag it over to the System Folder on the Hard Disk 20, replacing the old HD 20 Finder file.
 - f) Reboot the HD 20 Start-Up disk and recheck for the problem.

If it still exists, go to step 2.

2. Rebuild the HD-20's Desktop:

- a) Simultaneously press the COMMAND, OPTION and TAB keys while you reboot the HD 20 Start-Up disk.
- b) The Finder should ask if you want to initialize the HD-20. Make sure you select "Cancel" for this operation or you will lose all of the data stored on the HD 20.
- c) The Finder will then ask you if you want to rebuild the DeskTop file. Select OK. After the finder rebuilds its desktop, recheck for the problem. If it still exists, go to step 3.

WARNING: If you perform step 3 below, all data will be erased from the Hard Disk 20. This solution should be used as a last ditch effort, for a truly mangled hard disk.

3. Initialize the Hard Disk 20

- a) Press the COMMAND, OPTION and TAB keys while you reboot the HD 20 Start-Up disk.
- b) The Finder should ask if you want to initialize the HD-20. Select "OK". This operation erases all of the data stored on the HD 20.

Note that these methods will cure failures due to software Finder problems and will not get at hardware problems that may be the original cause of the problem. When finished with the above procedure, run the HD 20 Test located on the Startup disk on the hard disk.

Macintosh Plus: Serial Printer Damages SCSI Port

Revised: 7/22/88
Security: Everyone

Macintosh Plus: Serial Printer Damages SCSI Port

=====

Article Created: 23 January 1986
Article Last Reviewed: 17 July 1992
Article Last Updated:

PROBLEM DESCRIPTION: When a serial printer is plugged into the SCSI DB-25 port of a Macintosh Plus, the logic board is damaged and the logic board must be replaced.

CAUSE: Serial printers with DB-25 connectors commonly use the RS-232 electrical interface standard. The DB-25 port on the Macintosh Plus is a SCSI port, not an RS232 port. SCSI is a high speed parallel interface and is not compatible with RS-232. The chips used by the SCSI port in the Mac Plus may be damaged by the RS-232 signals from a serial printer.

CURE: Replace the Mac's logic board. To use a serial RS-232 device with the Mac Plus, use Apple's mini-circular 8 to DB-25 peripheral cable.

If the above cure doesn't fix the problem, refer to the Tech Procedures to obtain the general troubleshooting for this product.

Manzanita Software Systems: Version 5.10 of BusinessWorks

Revised: 1/25/86
Security: Everyone

Manzanita Software Systems: Version 5.10 of BusinessWorks

=====

Manzanita Software Systems released version 5.10 of BusinessWorks on January 22 with two new features:

1) The ability to load onto a RAM card with a minimum of 512K (1mb recommended). BusinessWorks programs are loaded into the RAM card memory, while company data is maintained on the 3 1/2" disk, so there's no chance of loss of data in case of power failure. A variety of RAM cards can be used, including Apple's Memory Expansion Card.

2) The ability to work with Pinpoint from Pinpoint Publishing, Inc. BusinessWorks users can access the Pinpoint desk accessories such as the calculator, calendar, clock, etc., while using BusinessWorks.

BusinessWorks users can get the new version directly from Manzanita Software.

Lisa Office System 7/7 Version 3.1: Migrating documents

Revised: 6/5/86
Security: Everyone

Lisa Office System 7/7 Version 3.1: Migrating documents

=====

There is only one version of the Migration software and it is intended to be used with Office System 7/7 Version 3.1.

When the Migration software is not properly installed, there are problems of functions not being available, such as the "Make Text File" option in the "File/Print" menu as per page 11 of the Macintosh XL Migration Kit manual. Drag copying the Migration Tool icon off of the second install disk without running the installation as described in the manual is a classic example of an improper installation of the Migration software

First off, make sure to install the Lisa-to-Macintosh application in the Lisa 7/7 or Lisa Workshop environment as per page 5 of the Macintosh XL Migration Kit manual. There are many files, invisible from the desktop, that are loaded during installation. Remember, installation requires you to boot the Lisa from the Install 1 diskette.

If error messages about unavailable functions appear while the Install disk is booting, replace the software with a new copy.

Macintosh: Using Print Buffers With ImageWriters

Revised: 8/5/92
Security: Everyone

Macintosh: Using Print Buffers With ImageWriters

=====

Article Created: 31 January 1986
Article Last Reviewed: 4 August 1992
Article Last Updated:

TOPIC -----

The article below is adapted from Dan Cochran's column "Answers from the Mac Team" in MacUser, February 1986, page 117.

DISCUSSION -----

A 32K print buffer has little or no effect when used with the Macintosh printing anything but text in Draft quality. For instance, if all MacWrite needed to do was send out a single byte of information for each character that it wanted to print, a serial buffer with 64K of memory would be able to receive and hold at least 20 pages of material and free up your Macintosh for other work while the printer was busy. If you're content with selecting Draft quality from the Print Dialog box, such a buffer device should work just fine. In Draft mode, the ImageWriter, acting like most serial printers, simply receives a sequence of single character codes (the ASCII set), one code for each character that is to be printed. For example, a typical MacWrite page of Geneva 12-point font will rarely exceed 3000 characters. The ImageWriter II optional buffer can handle the printing of up to 10 such pages in Draft Quality mode.

Because of the way the Macintosh sends information to the printer in the Standard and High Quality modes, a 32K buffer would not be large enough to hold even one page of information. To produce print quality better than Draft, the ImageWriter must receive much more information than simply a one-byte code per character.

Say you select High quality text from the Print dialog box and Tall Orientation from the Page Setup dialog box. This means that the ImageWriter will be printing 160 dots per inch horizontally and 144 dots per inch vertically. For an 8 inch by 10 inch printed page, the Macintosh

has to send enough information to the printer so that it can image $(160*8)*(144*10)$ or 1,843,200 dots. Each dot to be printed takes a bit of information to tell the printer whether the dot is supposed to be black or white. The printer can receive this information in 8-bit words, which, divided into the 1,843,200 dot/bits of the page, results in 230,400 words of memory (approximately 225K) needed in a print buffer device for storing even one page of MacWrite information. A buffer that could handle a 20-page document would need 2 megabytes of memory.

Some third party buffers have enough memory to make them effective print buffers on the Macintosh.

Macintosh: Mini Circular 8 Serial Port Pinouts (6/94)

Revised: 6/24/94
Security: Everyone

Macintosh: Mini Circular 8 Serial Port Pinouts (6/94)

Article Created: 31 January 1986
Article Reviewed/Updated: 23 June 1994

TOPIC -----

What are the pinouts for the mini circular 8 serial ports on the Macintosh Plus and later?

DISCUSSION -----

The two serial ports used on Macintosh computers since the Macintosh Plus are RS-422 mini-circular 8 pin connectors:

Pin	Signal
1	- HSKo (Data Terminal Ready)
2	- HSKi (Clear To Send)
3	- TxD- (Transmit Data -)
4	- GND (Ground)
5	- RxD- (Receive Data -)
6	- TxD+ (Transmit Data +)
7	- GPi (General-Purpose input); connected to SCC Data Carrier Detect (or to Receive/Transmit Clock if the VIA1 SYNC signal is high). Not connected on the Macintosh Plus, Classic, Classic II, LC, LC II, or IIsi.
8	- RxD+ (Receive Data +)

Looking at the end of a MALE mini-circular connector, the pins are:

6 7 8
3 4 5 The space is between pin 4 and 5
1 2

All Macintosh computers since the Macintosh Plus have the same mini-circular 8 pin connectors for their serial ports.

80-Column Text Card: Applesoft Control Codes (11/96)

Revised: 11/18/96
Security: Everyone

80-Column Text Card: Applesoft Control Codes (11/96)

Article Created: 1 January 1986
Article Reviewed/Updated: 14 November 1996

TOPIC -----

When you write BASIC programs while the 80-Column Text Card is active, there are a number of functions you can use by pressing the CTRL key in conjunction with another key. Functions activated by pressing these two-key combinations are called control character functions. Some control character functions work when you type them in from the keyboard as well as when used within PRINT statements in BASIC programs.

DISCUSSION -----

Table of Control Character Codes:

Key to Notes codes:

- 1 - Only available when 80-Column Text Card is active
- 2 - Only works from the keyboard, not in a program
- 3 - Only works in a program, doesn't work from the keyboard
- 4 - Not supported under BASIC

Control Character	ASCII Name	Apple IIe Name	ASCII Decimal Code	Notes	What is Executed
-----	----	----	----	-----	-----
CTRL-G	BEL	bell	7		Produces a 1000 Hz tone for 0.1 second
CTRL-H	BS	backspace	8		Moves cursor position one space to the left; from left edge of window, moves to right end of line above.
CTRL-J	LF	line feed	10		Moves cursor position down to next line in window; scrolls if

					needed.
CTRL-K	VT	clear EOS	11	1	Clears from cursor position to the end of the window.
CTRL-L	FF	clear	12	1	Moves cursor position to upper-left corner of window and clears window.
CTRL-M	CR	return	13		Moves cursor position to left end of next line in window; scrolls if needed.
CTRL-N	SO	normal	14	1,3	Sets display format normal.
CTRL-O	SI	inverse	15	1,3	Sets display format inverse.
CTRL-Q	DC1	40-column	17	1,3	Sets display to 40 columns.
CTRL-R	DC2	80-column	18	1,3	Sets display to 80 columns.
CTRL-S	DC3	stop list	19	1,2	Stops sending characters to the display until a key is pressed.
CTRL-U	NAK	quit	21	1,3	Deactivates 80-column Text Card, homes cursor, and clears screen.
CTRL-V	SYN	scroll	22	1	Scrolls the display down one line, leaving the cursor in the current position.
CTRL-W	ETB	scroll up	23	1	Scrolls the display up one line, leaving the cursor in the current position.
CTRL-Y	EM	home	25	1	Moves cursor position to upper-left corner of window (but doesn't clear).
CTRL-Z	SUB	clear line	26	1	Clears the line the cursor position is on.
CTRL-\	FS	forward	28	1	Moves cursor position one space to the right; from right edge window, moves it to left end of line below.
CTRL-]	GS	clear EOL	29	1	Clear line from cursor position to the right edge of the window.
CTRL-^	RS	gotoXY	30	1,4	Using the next two characters, minus 32, as one-byte X and Y values, moves the cursor position to CH=X, CV=Y.

The Apple 80-Column Card in an Enhanced IIe has some additional features documented in the Programmer's Guide to the Enhanced IIe.

Important Information About CTRL-U =====

A "CHR\$(21)" response (Control-U) to a "GET A\$" input statement in a BASIC program may disable the 80-column card on an Apple IIGS, Apple IIe, Apple IIc, and Laser 128 (but not an Apple II Plus with Applied Engineering's Viewmaster 80).

To halt the CONTROL-U function, the CONTROL-U keystroke needs to be trapped on input. Using the "GET A\$" method:

```
10 GET A$  
20 IF A$ = CHR$(21) THEN A$ = "" :REM traps the CONTROL-U, sets it to blank  
30 PRINT A$;  
40 GOTO 10
```

Instant Pascal: RGB Color

Revised: 1/31/86
Security: Everyone

Instant Pascal: RGB Color

=====

For the current release of Instant Pascal, the Extended 80 Column Color card is not activated at boot time. This was a deliberate design decision. Double high-res text, even with the 40 column option selected, does not look satisfactory on a Color 100 monitor (or other RGB monitors).

However, for customers who already have RGB monitors and who wish to use Instant Pascal in color, there is a pre-boot workaround to turn on the card. From ProDOS Basic, type and save the following program:

```
10 D$ = CHR$(4)
20 PRINT D$;"PR#3": PRINT
30 POKE 49246,0
40 POKE 49247,0
50 POKE 49246,0
60 POKE 49247,0
70 POKE 49246,0
80 CALL 50688
```

LOAD the program into your IIe and place the Instant Pascal STARTUP disk in the drive configured to Slot 6, Drive 1 and RUN the program. Instant Pascal will function as usual with the addition. Text will be difficult to read.

Instant Pascal: Transferring files to and from Apple II Pascal

Revised: 1/31/86
Security: Everyone

Instant Pascal: Transferring files to and from Apple II Pascal

=====

To transfer source code files from Instant Pascal (IP) to Apple II Pascal, you can make use of AppleWorks to massage the IP file type. Follow these steps:

1. Boot AppleWorks and load the IP source file into the word processor as "an ASCII file from disk."
2. Still using AppleWorks, print the file back to disk as an ASCII file.
3. Boot System Utilities 2.1 and copy the "printed" file from the ProDOS disk to an Apple II Pascal disk.

To transfer source code from Apple II Pascal to Instant Pascal, follow these steps:

1. Boot System Utilities 2.1.
2. Put the Apple II Pascal disk in one drive.
3. Put a ProDOS formatted disk in a second drive.
4. Select the Copy Files option from the System Utilities menu and copy the source code files from the Pascal disk to the ProDOS disk.

-- Note that System Utilities 2.1 supports file copying between two differently formatted disks.
5. The source file on the ProDOS disk will be recognized by Instant Pascal as a "Text" file, but you can open it into the Program window. If you save the file under Instant Pascal, it becomes an "IP" type file.

DuoDisk Problem/Cure: Copy Protected Disk Damaged During Boot

Revised: 1/17/92
Security: Everyone

DuoDisk Problem/Cure: Copy Protected Disk Damaged During Boot

=====

This article last reviewed: 24 February 1988

PROBLEM DESCRIPTION: When inserting a copy protected application or game into the DuoDisk and starting up the Apple II, II+, or IIfx system, the disk fails to boot. The disk may be damaged in the process.

CAUSE: If capacitors C29 and C30 are present on the analog PCB, they can allow unintentional writing to the disk. This problem can be triggered by certain copy protection schemes.

CURE: Clip off the capacitors C29 and C30 at locations B1 and A1 on the Duodisk Analog PCB.

If the above cure doesn't solve the problem, search on HTS and GTS and the product name to obtain the general troubleshooting procedure for the product.

LaserWriter P/C:Smudges 80-90mm From Print's Left Edge

Revised: 1/17/92
Security: Everyone

LaserWriter P/C:Smudges 80-90mm From Print's Left Edge

=====

This article last reviewed: 10 March 1988

PROBLEM DESCRIPTION: A print is made with a known-good, broken-in toner cartridge. The print is smeared or smudged in one spot or in a vertical column on the page approximately 80 to 90 millimeters (3 to 3 1/2 inches) from the left edge of the page.

CAUSE: 1. The thermoprotector on the fuser assembly may not be positioned improperly on the top fuser roller (see Figure 2-29 on page 2.44 of the LaserWriter Technical Procedures for proper thermoprotector positioning). Over time the toner builds up and because of the heat of the fuser assembly fuses to the thermoprotector. The mass of fused toner increases until it contacts the paper as it is entering the fuser smearing the print.

2. The four screws mounting the feeder guide may be unevenly adjusted causing the feeder guide to bend.

3. The feeder guide may be bent.

4. The paper may be charged with static.

CURE: 1. Check the thermoprotector for improper positioning against the upper fuser roller and toner build-up (refer to the LaserWriter Technical Procedures. Figure 16, item 4, on page 6.32 gives location and Figure 2-29 on page 2.44 for proper thermoprotector positioning). If the thermoprotector does not exhibit these symptoms, go to step 2. If it does, perform the following:

Use MEK (methyl ethyl ketone) copier cleaner/solvent solution (locally purchasable) to clean the thermoprotector. Do not replace the thermoprotector to solve the problem.

2. Completely tighten (DO NOT STRIP) all four screws mounting the feeder guide, back them off about a half turn so that all have approximately equal torque, then recheck for the problem. (refer to the LaserWriter Technical Procedures, Figure 2, item 2, on page 6.9 for location). If the problem remains, go to step 3.

3. Replace the feeder guide. Tighten the screws as described in step 2.

4. Fan the paper to help reduce any static charge that it may have accumulated.

If the above cure doesn't fix the problem, refer to the LaserWriter Tech Procedures to obtain the general troubleshooting procedure for this product.

512K Macintosh 800K External Drive P/C: Sad Mac error 0F0004.

Revised: 1/17/92
Security: Everyone

512K Macintosh 800K External Drive P/C: Sad Mac error 0F0004.

=====

This article last reviewed: 24 February 1988

BACKGROUND: The Apple 800K drive for the Macintosh requires the following software to run on a 128K or 512K Macintosh:

/HD20 Driver File

/System File Revision 3.0 or greater

/Finder File Revision 5.0 or greater.

A Macintosh Plus does not require the above listed software.

PROBLEM DESCRIPTION: Connect 800K external drive to Macintosh 512K (NOT upgraded to a Macintosh Plus). Boot up using Finder 5.0 or greater and System 3.0 or greater. Attempt to read an 800K disk from the external drive: Mac bombs with error ID=4. Attempt to initialize a 400K disk in the 800K external drive: Macintosh displays "Initialization Failed" dialog box. Attempt to boot an 800K disk on the external drive: Macintosh bombs with "sad Mac" error 0F0004.

CAUSE: The system file "Hard Disk 20" (the Hard Disk 20 driver) and the other files listed in "BACKGROUND" (above) are needed for the "old ROM" Macintosh to communicate with volumes (drives) larger than 400K. The necessary files may not be on the startup disk.

CURE: Install the files listed in "BACKGROUND" on your startup disk. If you don't have the files available, contact your local support center for copies. They are free of charge.

If the above cure doesn't fix the problem, refer to the Tech Procedures to obtain the general troubleshooting for this product.

Macintosh Plus : Won't Boot With SCSI Peripheral Off

Revised: 7/17/92
Security: Everyone

Macintosh Plus : Won't Boot With SCSI Peripheral Off

=====

Article Created: 3 February 1986
Article Last Reviewed: 17 July 1992
Article Last Updated:

PROBLEM DESCRIPTION: The Macintosh Plus won't boot with a powered off SCSI device connected.

CAUSE: Macintosh Plus boot ROM checks the SCSI port upon boot-up. If there is a SCSI device connected, the Macintosh tries to communicate with it. Of course, if the device is off, it will not respond and the Macintosh Plus will hang while it is waiting for a response from the SCSI device.

CURE: Disconnect the deactivated SCSI device or turn it on.

Apple Chip Service Part Numbers: Trivial Discrepancies

Revised: 11/10/88
Security: Everyone

Apple Chip Service Part Numbers: Trivial Discrepancies

=====

This article last reviewed: 10 November 1988

Quite often customers discover discrepancies in packing lists and actual parts received, most recently with the Apple IIe ROM Enhancement Kit. The story behind this problem also applies to ALL other Apple Chip part numbers, often called the service part number.

If (and only if) there are two chips:

1. when the four final digits of the part numbers are identical

and

2. when the the first three digits of the part numbers are 341 and 342,

then the chip with part number beginning with 342 has been burnt-in and the other has not.

Note: Do not infer that all chips with part numbers beginning with 342 have been burnt-in.

AppleWorks: Standard and Custom Printer Interfaces (1 of 2)

Revised: 8/10/87
Security: Everyone

AppleWorks: Standard and Custom Printer Interfaces (1 of 2)

=====

Versions of AppleWorks earlier than version 1.2 don't allow you to run Appleworks using any other interface card but the Apple Super Serial card. If you wish to use a different interface card, you must upgrade to 1.2 or later versions.

For a new owner of an Apple IIe with AppleWorks, dealers should include only those interface cards that work. The Silentype has its own interface card. Aside from that, there are two interface cards, the Apple II Parallel Interface Card (A2B0021) and the Apple Super Serial Card (A2B0044), that work correctly with all of the printers on AppleWorks' Add a Printer list:

1. Apple Printers
 - a. Dot Matrix Printer (DMP). AppleWorks is set up for the Apple DMP. If you have any other printer, you must set up AppleWorks for it.
 - b. Daisy Wheel Printer (DWP)
 - c. Imagewriter
 - d. Scribe
2. Epson (tm) Printer Series: MX, MX with Graftrax+, RX, and FX
3. Qume (r) Sprint 5 and Sprint 11

For new owners of a IIC, dealers should make sure that the customer's printer is compatible with a IIC running AppleWorks.

For a IIe owner considering AppleWorks, make sure the owner has a configuration compatible with AppleWorks. If the owner doesn't have such a configuration, the owner's only recourse to buy an interface card that is compatible.

--> Using AppleWorks with cards and printers not on the standard list

If you're using a card or a printer not on AppleWorks' standard list, you must add a custom printer to your AppleWorks configuration and specify the characteristics of the card or printer.

To choose the following options, type the number and press the RETURN key.

1. From AppleWorks' main menu, choose "5. Other Activities".
2. From the "Other Activities" menu, choose "7. Specify information about your printer(s)".
3. From the "Printer Information" menu, choose "2. Add a printer".
4. From the "Add a Printer" menu, choose "12. Custom printer".
 - a. Enter the name you wish to use for the printer.
 - b. Press RETURN.
 - c. Apple IIe: Choose the slot of the printer's interface card.
Apple IIc: Choose the port of the printer.
 - d. Press RETURN.
5. Press the ESC key: now the printer has been added to AppleWorks.
6. Now you must give AppleWorks what the printer needs to perform, specifying requirements for:
 1. a line feed after each carriage return,
 2. a top-of-page command,
 3. stopping at the end of each page,
 4. platen width,
 5. interface card settings, and
 6. codes for special functions of the printer.

Items 1 to 4 are self-explanatory and can readily be changed to meet the requirements of different jobs. You can do this from the "Printer Information" menu, choosing the printer you named under "Add a Printer".

7. With the Apple IIe, choose "5. Interface Cards". Now AppleWorks asks for a code to send to the printer interface card to prepare the card for sending data to the printer. Consult the table below for the appropriate keystrokes. (Note that [CTRL-] and the character in the bracket means that you must hold the CTRL key down while you type the character; do not type the brackets.)

Interface card	Code string
Apple Parallel Card (2PIC)	[CTRL-I]80N
Apple Super Serial Card	[CTRL-I]80N
Apple Centronix Parallel Card	[CTRL-I]255N
Grappler Plus	[CTRL-I]0N
Microtek RV-611C	[CTRL-I]255N
Pkaso	[CTRL-I]0N
MPC AP Graph and Graphwriter	[CTRL-I]255N

If your card isn't on this chart, look in the card manual; it should have the code string.

It's important to note that, although some printer manuals give code strings in the form of keystrokes, some other manuals give code strings in numerical form, either decimal (0 to 9) or hexadecimal (0 to F).

AppleWorks won't accept a code string simply typed in as one of these numbers; you must use a keystroke or combination of keystrokes to send the number from the keyboard to AppleWorks. Look up the decimal or hexadecimal form of the number in an Apple II ASCII chart; the appropriate keystrokes are on the right.

Suppose, for example, the manual states that the decimal code string 09464878 initializes the card. On an Apple II ASCII chart, 09 is [CTRL-I], 46 is the eight key, 48 is the zero key, and 78 is capital N; altogether, that's [CTRL-I]80N. To put this into AppleWorks you would:

1. Choose "5. Interface Card"
2. Hold down the CTRL key and type I,
3. Type 80
4. Hold down the SHIFT key and type N
5. Hold down the SHIFT key and type 6; this ends the string with the carat or '^' AppleWorks requires.

Tech Info Library Article Number:1711

Tech Info Library

AppleWorks: Standard and Custom Printer Interfaces (2 of 2)

Revised: 8/10/87
Security: Everyone

AppleWorks: Standard and Custom Printer Interfaces (2 of 2)

=====

8. With the Apple IIc and the Apple IIe, you must give AppleWorks what the custom printer needs to perform special functions. For each special function of the printer, you will have to enter a code using a combination of keystrokes that may not be immediately obvious. If you don't know the codes, have your printer manual nearby, and follow the instructions on pages 252 to 258 of the AppleWorks Reference Manual. Choose the option, perform the keystrokes that send the codes to AppleWorks, and then end the string by typing '^'.

For example, let's configure the custom printer driver to turn on the underline function of the fictitious printer, the ByteSpitter 1000.

1. From AppleWorks' main menu, choose "5. Other Activities".
2. From the "Other Activities" menu, choose "7. Specify information about your printer(s)".
3. From the "Printer Information" menu, choose the name of your custom printer under "Change printer specifications".
4. Choose "6. Printer Codes"
5. From Printer Codes choose "4. Underlining"

By checking with the ByteSpitter 1000 Reference Manual, we know that in order to turn on Underline Mode, the ByteSpitter 1000 requires the character string 'ESC U'. The command to stop underlining is 'ESC N'.

6. From Underlining choose "2. Printer has start/stop underline commands"
7. Choose "1. Underline begin"

The display will then show

Underline Begin

Current control characters are

None

'Type the exact control characters required (^ = End):' appears at the bottom of the screen.

8. Press and release the 'ESC' key

9. Hold down the SHIFT key and type U.

Case is very significant here. If the manual states that the printer needs a capital letter then it must be entered in upper case.

10. Hold down the SHIFT key and type '6' this ends the string with the carat or '^' AppleWorks requires for the end of the command string.

11. Choose "1. Underline end"

The display will then show

Underline End

Current control characters are

None

'Type the exact control characters required (^ = End):' appears at the bottom of the screen.

12. Press and release the 'ESC' key

13. Hold down the SHIFT key and type N.

14. Hold down the SHIFT key and type '6' this ends the string with the carat or '^' AppleWorks requires for the end of the command string.

Press the escape key five times to return to the main menu. To turn on underline in a Word Processing document, position the cursor on the first letter to be underlined, press Open-Apple-O and then type UB (underline begin). Underline will be in effect until the UE (underline end) command is entered or a carriage return is reached.

Try printing a document to your printer. If all is well, you can return to the printer setup portion of AppleWorks at any time and enter keystrokes to change or add codes for the printer's special features: superscripting, subscripting, boldface and different CPI. This information will be stored on the AppleWorks program disk for future use.

PostScript: Daisywheel emulator for the LaserWriter (1 of 2)

Revised: 2/8/95
Security: Everyone

PostScript: Daisywheel emulator for the LaserWriter (1 of 2)

Article Created: 2 May 1986
Article Reviewed/Updated: 8 February 1995

TOPIC -----

This article provides PostScript information for building a daisy wheel emulator for the LaserWriter. This information is provided by Adobe Customer Support. Apple Computer Inc. is not responsible for the contents of this article.

DISCUSSION -----

Caution

If you choose to use the PostScript code provided in this article, you assume all risks involved in making these changes. PostScript code, if not entered correctly, can place the LaserWriter into a condition requiring service.

Below is a generalized PostScript program that provides a framework for building ANY daisy wheel emulator. Anyone with knowledge of PostScript will be able to figure out how to customize this program to meet their special needs. Unfortunately the sensitivity to ^C^D^T^S^Q,CR,LF is not avoidable.

```

TOPIC -----

This is part 2 of an article that describes how to build a daisywheel emulator for a LaserWriter printer. This information is provided by Adobe Customer Support. Apple Computer, Inc. is not responsible for the content of this article.

DISCUSSION -----

Caution:
=====

If you choose to use the PostScript code provided in this article, you assume all risks involved in making these changes. PostScript code, if not entered correctly, can place the LaserWriter into a condition requiring service.

Apple IIGS: 5.25 System Utilities

Revised: 10/6/86
Security: Everyone

Apple IIGS: 5.25" System Utilities

=====

To organize a user's disks, the Apple IIGS System Utilities program formats and copies disks and can copy, rename, and delete files, performing most of these functions on 4 of the Apple II operating systems: DOS 3.3, ProDOS, Pascal, and CP/M. Distributed on a 3 1/2" disk, the program works only on the Apple IIGS.

You can create a 5 1/4" floppy disk version of the program using the System Utilities in the following steps:

1. Format a 5 1/4" disk
2. Copy these 5 files from System Utilities to the 5 1/4" disk:
 - a. P8
-- This is ProDOS - found in the SYSTEM sub-directory.
 - b. SYSUTIL.SYSTEM *
 - c. GSSU0 *
 - d. GSSU1 *
 - e. GSSUE1 *

* These 4 files comprise the System Utilities program, and can be found in the SYS.UTILS sub-directory. They must be kept in the same directory.
3. Rename the file 'P8' to 'PRODOS'

System Utilities may now be booted from the floppy disk. The files take up around 180 blocks and leave about 100 blocks for extra file storage.

Macintosh: Erasing Parameter RAM

=====

Just as Preferences in the Lisa keeps the settings, the Parameter Memory chip or Parameter RAM in the Macintosh maintains system information: Clock, date, and alarm settings, some Control Panel settings, and Serial port configurations.

If necessary, Parameter RAM may be erased entirely:

1. Turn off the Macintosh
2. Unplug the Macintosh
3. Remove the battery (do not try to draw off charge by placing the battery back in upside down)
4. After at least 10 minutes, reinsert battery

Centronics 702 or 703

=====

The Centronics printer interface was originally designed to be used with the Centronics microP-1 printer. That printer required a control character to set it into 80-column mode. The firmware on the Centronics printer interface, PROM P9-00, sends a \$1D when ever it receives the <CTRL-I>80N command. This control character is part of a VFU command on a Centronics 702 or 703 and usually deselects the printer. The fix is to send a re-select code, but since the deselected printer doesn't return the Apple's handshake, the reselect will have to be POKEd to the interface, as follows:

```
100 FOR J = 1 TO 5
110 POKE -16256 + 16 * SL, 17
120 NEXT
```

LaserWriter Plus Upgrade: Description Of Features

Revised: 11/10/88
Security: Everyone

LaserWriter Plus Upgrade: Description Of Features

=====

This article last reviewed: 6 February 1986

Features include:

1. a revised LaserWriter Plus manual,
2. 16 ROMs and socket with jumper block,
3. New LaserWriter driver.

The upgrade consists of 16 512K ROMs and a DIP socket with a jumper block. These are placed into the I/O board by the dealer. Pre-November 1985 production boards do not have the DIP socket and will need to have it installed. Boards built after the cut in date will have a socket and jumper block installed at the factory. Dealers have the option of having the upgrade done by Apple by requesting a service board in advance and then sending in the old board.

The new 512K ROMs contain 7 new fonts in 2 typefaces. The new fonts are:

1. ITC Avante Garde Gothic
2. ITC Bookman
3. Helvetica Narrow
4. New Century Schoolbook
5. Palatino
6. ITC Dingbats, a font of special characters, stars, bullets, etc., in plain style only.
7. ITC Zapf Chancery, a script font, in italic style only.

Fonts 1 through 5 are in plain, bold, italic, and bold italic styles.

All fonts are sublicensed from Adobe Systems.

With the addition of these fonts, the LaserWriter Plus now has 11 built-in fonts with 35 individual typefaces. It's not possible to print Symbol-letters bold on the LaserWriter Plus. The Symbol Bold font was removed from the LaserWriter Plus ROM's to accommodate more fonts.

To speed output, use the new LaserWriter driver with the Macintosh Plus ROMs. LaserWriter 3.0 or greater will facilitate fractional pixels with LaserWriter or LaserWriter Plus. The application must enable this feature in the 128K ROMs.

Also, make sure that you copy LaserWriter fonts into the System File with the Font/DA Mover version 3.0 or later if you are using the the LaserWriter driver version 3.0 or later.

LocalTalk: Alternate Sources For Cable

Revised: 11/2/88
Security: Everyone

LocalTalk: Alternate Sources For Cable

=====

This article last reviewed: 6 February 1986

Many large accounts are installing AppleTalk networks. For custom length LocalTalk cables, there are two resources, Apple dealers and third-party vendors.

Apple dealers have Apple's LocalTalk Custom Wiring Kit. You must consider if the account has the assembly skills required by the kit. Even though this kit was introduced with large installations in mind, it may fall short of fulfilling the account's requirements. Each kit contains the necessary materials to construct 8 cables of varied lengths. Unfortunately, the account must buy a second kit just for its connectors if more than 8 are needed (and the total network does not exceed 1000 feet). Sometimes buying supplementary 10 meter cables solves this problem.

Third-party vendors will accept specifications for custom cables. These cables are pre-assembled and using them requires nothing beyond the usual skills needed for a normal installation. The higher cost of this cable can bring up the cost of total installation, however.

Here are some vendors of custom length cables:

Advanced Electronics Support Products, Inc.
18909 N. E. Fifth Avenue
North Miami, FL 33179

Macintosh: Bi-directional Printing on an ImageWriter (10/93)

Article Created: 21 April 1986
Article Reviewed/Updated: 6 October 1993

TOPIC -----

This article describes uni-directional and bi-directional printing on the ImageWriter and ImageWriter II.

DISCUSSION -----

ImageWriter (original) - all Driver Versions, cannot be overridden:

High	Bi-Directional	Always
Standard	Uni-Directional	Always
Draft	Bi-Directional	Always

ImageWriter II - with Driver Version 2.0, cannot be overridden:

High	Bi-Directional	Always
Standard	Bi-Directional	Always
Draft	Bi-Directional	Always

ImageWriter II - with Driver Version 2.1, 2.2, 2.3, 2.5, 2.6 or 7.0.1:

High	Bi-Directional	Always
Standard	Uni-Directional	Default
	Bi-Directional	In the Print Dialog box: hold down the OPTION, SHIFT, and CAPLOCKS while clicking OKAY
	Undo Bi-Direct.	In the Print Dialog box: hold down the COMMAND (Feature) key while clicking OKAY
Draft	Bi-Directional	Always

Note: Screen dumps are always Uni-directional.

AppleWorks: Printing in color on the ImageWriter II

Revised: 10/12/87
Security: Everyone

AppleWorks: Printing in color on the ImageWriter II

=====

This article last reviewed: 9 October 1987

Apple Works can print in color on the ImageWriter II. To enable color printing, configure a custom printer, and select printer codes that you do not expect to use, e.g. 4 character per inch, superscript start and stop, etc. Define those codes with the escape sequences for the color you wish to implement. For the correct codes, refer to Appendices F and G in the ImageWriter II Owner's Manual and the ImageWriter Quick Reference Card in the rear of same.

A typical set up is as follows:

Code	Effect
CTRL-N	4 CPI
CTRL-O	10 CPI
ESC K 2	5 CPI used for Red
ESC K	6 CPI used for Blue
ESC !	Boldface begin
ESC "	Boldface end
ESC y	Sub begin
ESC z	Sub end
ESC x	Super begin
ESC z	Super end

With this set up, printing a portion of text in red requires the following steps:

1. Move the cursor to the beginnning of the desired text.
2. Select printer options.
3. Choose 5 CPI.
4. When you want to return to black printing, select printer options and choose 10 CPI.

To set the printed text to blue, select printer options and choose 6 CPI.

Don't forget to select printer options and choose 10 CPI to return printing to black.

Use these steps to produce color printing of one word or a couple of words. To make a whole paragraph color, the only command that seems to work consistently is underline. If you configure the underline command as a color, you'll get the whole paragraph in that color. If you configure the superscript-subscript command as a color, you'll only get the first line in color; all subsequent lines will be black. Margins will be wrong if you set up things like 4 CPI for color.

Extended 80-Column RGB Card: Color Monitor 100 Pinouts (11/96)

Revised: 11/18/96
Security: Everyone

Extended 80-Column RGB Card: Color Monitor 100 Pinouts (11/96)

Article Created: 19 April 1991
Article Reviewed/Updated: 14 November 1996

TOPIC -----

Does the Extended 80-column card work in the Apple II or Apple II Plus? If not, is there any way to upgrade an Apple II or Apple II Plus to 80-Column?

DISCUSSION -----

The 80-Column Card and Extended 80-Column Card work only in the Apple IIe; they cannot be used in any other computer.

Our databases do not show an 80-column interface for the Apple II or Apple II Plus. There were once several on the market, but the demand for this type of card has almost disappeared. You might still be able to find these 80-column cards through some of the computer remarketing companies, or where use computer equipment is sold.

An alternative is to purchase an Apple IIe or Apple IIGS computer. You need to to contact computer remarketing companies, or look where use computer equipment is sold.

Macintosh Pascal 1.0: Error ID=02 on 512K with no external drive

Revised: 2/12/86
Security: Everyone

Macintosh Pascal 1.0: Error ID=02 on 512K with no external drive

=====

On a 512K Macintosh with no external drive attached and any Finder (1.1, 4.1, or 5.0), Macintosh Pascal bombs with a system error ID=02 when executing the following Pascal program:

```
program Bomb;
var
  r : real;
  outfile : text;
begin
  rewrite(outfile, 'Data Disk:Sample File');
  r := 0;
  writeln(r : 5 : 2);
  writeln(outfile, r : 5 : 2);
end.
```

Using the step-step feature of Macintosh Pascal, the next line to be executed when the bomb occurs is "r :=);".

To get this error:

1. Insure that the external drive is not connected. The system must have one drive only.
2. Boot with Macintosh Pascal disk.
3. At the desktop, eject the Macintosh Pascal disk.
4. Insert a blank disk and name it "Data Disk".
5. Eject this disk. Do NOT put it in the trash - the disk must still exist on the system.
6. Open Pascal document "Bomb", the program above.
7. Execute the program either with the command "go" or "step-step".

8. Insert the disk "Data Disk" when the message asking for it appears.

This problem has two work arounds:

1. Move the statement "r := 0;"
before the statement "rewrite(outfile, 'Data Disk:Sample File');"
2. As a general practice, place the File definition var FIRST.

MacTerminal 2.0: Issuing Breaks

Revised: 9/1/87
Security: Everyone

MacTerminal 2.0: Issuing Breaks

=====

A Macintosh Plus can run MacTerminal 2.0, but the new Macintosh Plus keyboard cannot produce a "Break" in the same way.

Among others, users of Northern Telecom SL-1 PBX are affected by this change.

To work around the problem:

1. Use the 'Option' key on the new Macintosh Plus keyboard.
 - a. Break (0.2 sec): Option, Enter
 - b. Long Break (2 sec): Option, Shift, Enter
2. For short Break (0.2 sec), use the Apple Cluster Controller's "Attn" on the Pull-Down-Keypad.
3. When using the OLD keyboard: use the Enter key on the Keyboard only. (NOT on the Numeric Keypad):
 - a. 3278 mode: Long Break (2 sec): Shift, Enter
 - b. VT-100 mode:
 1. Break (0.2 sec): Enter
 2. Long Break (2 sec): Shift, Enter

Scribe: Printing the apostrophe in letter quality mode

=====

When the apostrophe appears in a almost horizontal position on a Scribe printing in letter quality mode, some people feel that:

1. there is something wrong with their Scribe
2. the Scribe has old ROM's which surely have been upgraded to take care of such a noticable problem.

Neither explanation is true. In regular mode, the Scribe prints a conventional apostrophe.

TITLE

Macintosh: System Error Codes Explained

Article ID: 1749
Created: 2/18/86
Modified: 1/11/00

TOPIC

This article explains what some Macintosh system errors actually mean. You can use them to interpret what is happening when your Macintosh gives these errors.

DISCUSSION

Because the Mac OS is a sophisticated, complex operating system, the difficulties a user encounters can be equally complex.

These are examples of some difficulties that may occur:

- A handle can be de-referenced.
- A routine can get a NIL pointer.
- The stack can dip into the heap for just a few cycles and not be caught by the stack sniffer.
- An application can forget to check an error code.

A Macintosh computer usually crashes with a system error code while running under System 6.0.x. Starting with System 7, errors are displayed in a different fashion. Instead of displaying an error code, the system translates the code to the appropriate words, like "Address Error".

Finding out what's wrong involves use of debugging tools, intricate knowledge of Macintosh memory structures, and familiarity with the application itself. Fixing it usually involves recompiling the source code. The table below explains some of the codes.

ID=01 Bus Error

This means the computer tried to access memory that doesn't exist. You can get this error on almost any Macintosh computer. If one of these computers tried to access one or more bytes beyond the total number of bytes in RAM, you see a bus error. You should never see this error on a Macintosh Plus or SE, because address references that are out of bounds "roll over." This means if one of these computers tries to access one byte beyond the total bytes in RAM, it actually accesses the first byte in memory. If you see this error on a Macintosh Plus or SE, it's reporting the wrong error or experiencing hardware failure.

ID=02 Address Error

The Motorola 68000 microprocessor can access memory in increments of one byte (8 bits), one word (16 bits), or one long word (32 bits). The microprocessor can access a byte of information at an odd or even memory address. But it must access a word or long word at an even memory address. So, when the microprocessor attempts to read or write a word or long word at an odd address, you see this error. Since that's a 50/50 proposition when running random code, this one shows up quite often.

ID=03 Illegal Instruction

The computer has a specific vocabulary of machine language instructions it can understand. If a computer tries to execute an instruction that isn't in its vocabulary, you see this error code. It's less likely than error 02, but still very common.

ID=04 Zero Divide Error

This error results if the microprocessor divides two numbers, and the divisor is zero. Sometimes a programmer puts these in as debugging aids, and then forgets to take them out.

ID=05 Range Check Error

Programmers can use an instruction in the Motorola 68000 to check if a number is within a certain range. This error indicates that the number tested isn't in the specified range.

ID=06 Overflow Error

..TIL01749-Macintosh_System_Error_Codes_Explained.pdf

Each number stored in a computer is given a certain amount of space. The larger the number, the more space is needed to represent the number. An overflow condition results if a generated number is too big for its allotted space. A Motorola 68000 instruction tests for an overflow condition, and displays this error if it detects an overflow.

ID=07 Privilege Violation

The Motorola 68000 runs in Supervisor or User mode. The Macintosh computer should always be in Supervisor mode, but sometimes is placed in User mode. Some of the instructions can only be executed in Supervisor mode. If the computer attempts one of these instructions while in User mode, a Privilege Violation error results.

ID=08 Trace Mode Error

A programmer can use a runtime debugger while in Trace mode. This allows tracing through a program one instruction at a time. You see this error if a debugger isn't installed and the 68000 is accidentally placed in Trace mode.

ID=09 and ID=10 Line 1010 & 1111 Trap

There are many routines in the Macintosh ROM that can be called by placing instructions in a program that aren't in the 68000's vocabulary. When the 68000 encounters such an instruction, it looks it up in the instruction table. This table gives the location of routines paired with each instruction. If it finds an entry in the table for the instruction, it branches to the routine. If there's no entry for the instruction, you see one of these errors.

ID=12 Unimplemented Core Routine

A programmer might set breakpoints in parts of a program to inspect for errors. This requires using a debugger. If a debugger isn't installed when a breakpoint occurs, you see this error code.

ID=13 Uninstalled Interrupt

The Macintosh uses an interrupt to identify when devices like keyboards and disk drives need service. Routines must be available in memory to tell the computer how to service the device. If those routines aren't available, you see this error.

ID=15 Segment Loader Error

Macintosh programs are broken up into segments, and each program will always have at least one segment. Multiple segments allow loading parts of the program into memory to provide more room for data in internal RAM. The segment loader is responsible for loading a needed segment into RAM. If the segment loader can't do this, you'll see this error.

ID=17 through ID=24 Missing Packages 0-7

The Macintosh uses packages to do specific tasks. Some of the packages are International Utilities, Binary-Decimal Conversion, Standard File Utilities, and Disk Initialization. These packages are located in the System file. If you get these errors, you probably have a damaged System file. Error codes 15, 16, 26, 27, 30, and 31 also come up when the System file is damaged. Try replacing the System file.

ID=25 Memory Full Error

You've probably run out of RAM. But you can get this error when an earlier error causes the Macintosh to falsely detect an out-of-memory condition.

ID=26 Bad Program Launch

The computer couldn't execute the application opened.

ID=28 Stack Ran into Heap

This is similar to the Memory Full error. It's a good idea to save your work frequently, and keep current backups of your hard disk data. When a system crash does occur, you'll lose less data if you've taken these precautions.

Other error codes can be found in the following Tech Info Library articles:

Article 9804: [**"Mac OS System Error Codes: -299 to -5553"**](#)

Troubleshooting System Errors

It's a good idea to save your work frequently, and keep current backup copies of your hard disk data. When a system crash occurs, you'll lose less data if you've taken these precautions.

..TIL01749-Macintosh_System_Error_Codes_Explained.pdf

If you're getting system errors frequently, investigate these possibilities:

- Try to open the document with a current version copy of the application.
- Try opening other documents with the same copy of the application.
- Check to see if the document size exceeds the application size limits.
- Boot your system with extensions off (restart while pressing Shift).
- Any changes (new Control Panels, extensions, and so on.) you've made to the system might give you a clue to the cause of the crashes.
- Make a note of the desk accessories you had open at the time of the crash and exactly what you did before the crash.
- Make a note of the error ID or text, and the version numbers of the application and system software you were using.
- Try to recreate the behavior on another Macintosh computer.
- Perform a clean installation of your system software and try the application again.

Macintosh Plus SCSI Port: No Termination Power

Revised: 7/16/92
Security: Everyone

Macintosh Plus SCSI Port: No Termination Power

=====

Article Created: 19 February 1986
Article Last Reviewed: 2 July 1992
Article Last Updated: 2 July 1992

If a Macintosh Plus attached to a SCSI device hangs on power up, make sure that at least one device attached to the SCSI port is powered on.

Most other Macintoshes with the exception of PowerBooks, provide termination power (pin 25). The Macintosh Plus does NOT supply termination power because of power supply limitations. In a situation where the Macintosh Plus and the SCSI device don't boot properly, check with the SCSI device manufacturer to make sure the device is not expecting termination power from the Macintosh Plus.

Note also that even though the SCSI port is a DB-25 connector, it should not be used to connect any other serial or parallel devices. ONLY SCSI DEVICES should be attached to the SCSI port.

TOPIC -----

This is the first part of a two-part article on the Small Computer Systems Interface (SCSI) used in Macintosh computers.

DISCUSSION -----

History

Small Computer Systems Interface (SCSI or Scuzzy), a second generation development, was submitted to ANSI in 1982 for acceptance as a systems interface between computers and other peripherals. In its first generation, it was known as SASI or Shugart Associates Systems Interface, which Shugart developed for the commercial market between 1980 and 1982, designing it primarily as a system interface for disk drives. While employing the multiuser and bus arbitration of SASI, SCSI adds features and host processors on the bus. SCSI also insures full user device independence and allows the bus to handle differential drivers and receivers, increasing the speed and distance capability of the bus.

The European Computer Manufacturers Association (ECMA) is currently working on their own version of the SCSI document. No specific release date has been mentioned.

Function

With its simple arbitration scheme and well-defined command set, the SCSI bus can form the backbone of multi-processing and smart I/O systems that coordinate as many as eight SCSI adapters and controllers. Each SCSI controller can govern as many as eight peripherals, with an option to expand that number to 2048 (per SCSI controller). The network may be as

long as 25 meters for differentially driven signals or 6 meters long for single-driven devices.

Bus access and user arbitration

Two arrangements can interface the unit with the SCSI bus:

1. 50 pin
 - a. Differential driven signals
 - b. Maximum data transfer rate per user: 4 Megabytes
2. 25 pin
 - b. Single-wire driven signals
 - b. Maximum data transfer rate per user: 1.5 Megabytes

Apple Macintosh Plus supports a data transfer rate of 320 Kbytes/second. The Macintosh also uses a DB-25 connector identical to the RS-232 interface - which may lead to user identification problems in the future.

The network interface specifies the eight data lines (0 to 7) on the SCSI connector as device-ID lines, which serve as user addresses. SCSI resolves bus contention by address priority along with the status of the BSY (busy) and SEL (Select) lines. To initiate a transaction, a device first checks the control lines to determine if the bus is in use. If the BSY and SEL lines are not active, the device sets BSY and its own specified user-ID line (0 to 7). The highest selected line wins bus access, with all the other users deferring.

The ANSI specification does not detail address priority. Generally, assign higher priority to devices that are not fully buffered or that have smaller buffers. Lower priority should go to devices, such as printers, that have large buffers because they can allow deferred bus access to a greater degree than the buffers of limited storage devices.

The highest priority user first asserts its ID. After that, while still maintaining its device-ID line, the user raises the SEL line to signal bus arbitration, then raises the device-ID line of the device it wishes to communicate with, and then drops BSY, whereupon the selected device then raises BSY to complete the sequence. Once the arbitration stage is over, the devices move into either the MESSAGE or the COMMAND stage.

Bus utilization

Like ABLAP protocol, bus arbitration reduces network overhead time by not requiring data transfer between network users. Another measure of efficiency is the channel usage involved in actual data transfer, not in system control or system status, with system degradation increasing as more users try to get on the bus. Results from a test at NCR indicate that SCSI achieves better than 50% channel usage, well above the 30% channel usage designers generally consider as the maximum allowed. These results were obtained in laboratory conditions, but it still appears that SCSI is a great improvement over other data transfer schemes between multiple processors on a common bus.

TOPIC -----

This is the second part of a two-part article on the Small Computer Systems Interface (SCSI) used in Macintosh computers.

DISCUSSION -----

Concurrent bus activity

SCSI uses 'smart' controllers which can enhance bus usage so that initiators as well as targets can contend for the bus (which is why arbitration is needed in a multiprocessor environment). A target system, through its control unit, may contend to re-establish a connection with an initiator that has requested the target to perform some task. The target system's control unit can relinquish the bus so the unit and the system can make better use of the time it takes to respond to a command from an initiator. Subsequently, once the peripheral is ready to interact with the initiator again, the control unit can contend for the bus. After winning arbitration, the control unit reselects the initiator by raising the proper control lines. In this way, devices like tape drives and printers can temporarily disconnect when their buffers are full, allowing other operations to continue at the same time. This parallel activity is called MULTITHREADED I/O.

Message stage functions

A system must support the full SCSI implementation in order to send messages on the bus. This MESSAGE phase is necessary for setting up local conditions (ie., synchronous data transfer, etc..) for the following COMMAND stage.

The 'Identify' message establishes the physical data path between an initiator and a target. During this process, the initiator's processor on the SCSI bus (called the Host) saves a set of pointers that describe the current buffer location in the Host's memory. If the target then chooses to disconnect to perform its command or task, the saved pointers define the same buffer location when the target re-establishes the connection to the initiator. If either the target or the initiator cannot support messages, the target goes directly to the COMMAND phase. In this case, the target cannot disconnect until the data exchange is complete.

Command stage functions

The SCSI commands provide for many system tasks. The Enquiry command, for example, permits the SCSI system to determine the configuration of I/O processes without having the entire system on the bus go through a system definition regeneration. The I/O device responds to the Enquiry command by telling the initiator what type of device the I/O unit is and how to communicate with it. If the system software implements an Inquiry command as part of its initial booting process, the host can identify the characteristics of all the devices on the system at that time, eliminating a great deal of operator intervention and overhead.

Other commands allow peripheral control units to assign block numbers to the peripherals they control. The Logical Block Addresses (LBAs) usually refer to a single physical sector of a peripheral; however, they may also be part of a physical block or multiple physical blocks. A collection of contiguous logical blocks is known as a Logical Unit (LUN). A LUN can refer to a part of a peripheral (for example, one disk in a multi-disk drive), a single peripheral, or a group of peripherals, depending how the control unit is set up. This means that a control unit needs only to specify a LUN and LBA instead of a drive, cylinder, head, and sector address when addressing a random-access drive.

Data transfer modes

Data transfers between selected devices may be in either asynchronous or synchronous mode. Synchronous data transfer must be specified by both bus users during the command mode, otherwise data transfer mode defaults to asynchronous mode. During asynchronous mode, the REQ(request) and ACK(acknowledge) bus-control signals control the data pacing on a byte-by-byte basis between the two units, with a maximum data rate of 1.5 Mbytes/second. Synchronous data transfers involve a series of REQ commands and data without the immediate receipt of corresponding ACK signals, allowing a faster data transfer rate of up to 4 Mbytes/second. ACK signals sent by the receiving device are used to verify individual data byte transfers, with a pre-established offset between the actual transfer of a specific data byte and its acknowledged receipt. This REQ/ACK offset is part of the synchronous data transfer control agreed to by both parties beforehand.

RS-232 Cables: Maximum acceptable length depends on data rate

=====

Article Created: 18 February 1986
Article Last Reviewed: 9 June 1992
Article Last Updated:

TOPIC -----

Is there a way to figure out the maximum length of RS-232 cables?

DISCUSSION -----

The maximum length of RS-232 cables is related to the data rate. Thus, you can calculate maximum cable length based on the data rate. The table below provides the maximum length of RS-232 cables (average cable and special cable) for the various data rates.

Data rate (baud)	Maximum acceptable Feet of average cable	Maximum acceptable Feet of special cable
-----	-----	-----
19200	50	83
9600	100	163
4800	200	326
2400	400	652
1200	800	1304
600	1600	2608
300	3200	5216

Average cable is defined by its capacitance, 50 picofarads (pf) per foot. Special cable is defined by a lower capacitance, 30 pf/foot, which makes special cable more costly.

The top line of the table is defined by interface standard RS-232C. We have made the remaining lines stay within the standard by taking the next highest line and halving the baud rate to double the length.

How the Top Line Was Determined

The RS-232C interface standard was set by and is available from the Electronic Industries Association (EIA), Engineering Department, 2001 Eye St., Washington, D.C., 20006. Several data reference manuals and booklets also contain and explain the standard. Apple uses the EIA RS-232C interface standard for all of its serial printer and communications interface equipments (excluding any parallel interface or item on AppleTalk).

We have used this standard to determine maximum cable length by referring to the specified amount of integrity of the transmission of data through the cable. This amount of integrity is specified in terms of maximum signal distortion at the maximum cable capacitance and at the maximum data rate.

For cables, the standard specifies the following maximum limits:

- Time Data Signal Distortion: 1 millisecond or 4 percent, whichever is greater.
- Cable Capacitance: 2500 picofarads (pf)
- Data Rate: 20,000 bits/sec.

Because the highest supported data rate is 20Khz (only the Macintosh can go as fast as this), there is some "fudging" allowed for cable distance. As no maximum distance between units is called out, all the cable has to do is provide a connection that meets the distortion and capacitance limits while supporting the data rate.

Most data cable has an average capacitance of 50 picofarads per foot. 50 feet of such cable would have a capacitance of 2500 picofarads, the maximum allowable capacitance.

Special, more costly, low-capacitance cable with less than 30 pf/foot would have a capacitance of 2500 pf or less in a length of around 83 feet. Depending on the actual capacitance, the low capacitance cable could be a lot longer, as long as its total capacitance stayed under 2500 pf.

Pascal III: Mapping of SOS error codes

=====

Pascal III maps SOS error messages 1 to 5 as Pascal error numbers 123 to 127 because of a numbering conflict.

For example, a user of Great Plains software, a Pascal III-based software package, posted Accounts Receivable and encountered a system crash during the merge or printing of the sorted sales journal. The system reported SOS error 123, so the error was really SOS error 01, Invalid SOS call number.

ProDOS: Saving the LoRes screen image

=====

ProDOS gives the 'NO BUFFERS AVAILABLE' message when you try to load a file, such as a saved text or LoRes screen image, into already used memory. Since the text screen area is marked as inuse by the system, ProDOS can not load the saved screen shot.

A solution makes that memory show as free while loading the picture:

```
10 A=PEEK(48984) : REM save the current memory bitmap area
20 POKE 48984,192 : REM Tell ProDOS that the Screen memory is not used
30 PRINT CHR$(4);"BLOAD IMAGE,A$400" : REM load in the screen file
40 POKE 48984,A :REM and put the bitmap back the way we found it
```

Macintosh Plus: Specifications (Discontinued 10/90)

Article Created: 19 February 1986
Article Reviewed/Updated: 19 June 1992

TOPIC -----

This article gives the technical specifications for the Macintosh Plus computer.

DISCUSSION -----

MICROPROCESSOR

- Motorola MC68000, 32-bit architecture, 8 (7.8336) MHz clock speed

MEMORY

- 1 MB of RAM (Random Access Memory), up to 4 MB using 1 MB SIMMs (Single Inline Memory Modules), 150ns or faster
- 128K of ROM (Read Only Memory)

DISK DRIVE

- One built-in 800K disk drive. (Optional external 400K or 800K disk drive.)

SCREEN

- Built-in 9-inch diagonal, 512 by 342-pixel high-resolution bit-mapped monochrome display

INTERFACES

- Mouse port, DB-9 connector
- One eight-bit keyboard bus, 300 baud, RJ11 connector for Macintosh Plus Keyboard
- Two RS-232/RS-422 serial ports, 230.4K baud maximum (up to 0.920 Mbit per second if clocked externally), circular Mini DIN-8 connectors
- SCSI interface
- External Disk Drive interface (400K or 800K disk drives)
- Sound port for external audio amplifier or headphones

CLOCK/CALENDAR

- CMOS custom chip with 4.5 volt battery backup (Eveready No. 523 or equivalent)

ELECTRICAL REQUIREMENTS

- Line voltage: 105 to 125 volts AC
- Line frequency: 50 to 60 hertz
- Maximum power: 60 watts

ENVIRONMENTAL REQUIREMENTS

- Operating temperature: 50 to 104 degrees F (10 to 40 C)
- Storage temperature: -40 to 122 degrees F (-40 to 50 C)
- Relative humidity: 5% to 90% relative humidity
- Altitude: 15,000 feet (4615 meters)

SIZE AND WEIGHT

- Height: 13.6 inches (34.5 cm)
- Width: 9.6 inches (24.4 cm)
- Depth: 10.9 inches (27.6 cm)
- Weight: 16 lb. 8 oz. (7.5. kg)

Macintosh Plus: Using the AppleTalk DB-9 connection module

=====

Article Created: 19 February 1986
Article Last Reviewed: 2 July 1992
Article Last Updated:

To use the DB-9 AppleTalk connection module (used with Macintosh 128K and 512K models) with the Macintosh Plus you will need to either use the Apple DB-9 to circular 8 adapter cable (part 590-0553 or 590-0341) or make an adapter cable with the following pinouts.

Macintosh Plus: Circular 8 to DB-9 Adapter Pinouts

Circular 8	Signal	DB-9
1	HSKo (+12V)	6
2	HSKi	7
3	TXD-	5
4	GND	3*
5	RXD-	9
6	TXD+	4
7	No Wire	
8	RXD+	8
	GND	1*

* Pins 1 and 3 on the DB-9 end are jumpered together.

The pins on the male end of the circular 8 connector are numbered as shown:

6 7 8
3 4 5
1 2

The pin assignments for the DB-9 connector on the AppleTalk connection module are as follows:

Signal Name	Pins
	DB-9

RXD+	8
TXD+	4
RXD-	9
TXD-	5
Case ground	DO NOT DIRECT CONNECT CASE GROUND TO CABLE SHEILD.

The case ground signal goes from the connector module shell through a ground isolation network in the connector module to the shield of the cable. The ground isolation network isolates grounds and helps prevent ground currents. No further case grounding should be made.

Daisy Wheel Printer: Specifications (Discontinued)

=====

Article Created: 20 February 1986

I. Technical Specifications

- A. Print Speed: 40 characters per second (average)
- B. Interface: Asynchronous Serial (RS-232C) OCITT-V-24
- C. Forms: Single sheet or continuous forms
 - Maximum width: 15 inches (38.1 cm)
- D. Fonts: 130-character "daisy" print wheels in various alphanumeric type styles, including: Courier 10 pitch, Prestige Elite 12 pitch, Gothic 15 pitch, and Executive/Boldface in English, French, German, and many other languages.
- E. Character Spacing in characters per inch (CPI):
 - 1. 10
 - 2. 12
 - 3. 15
 - 4. Proportional spacing
 - Maximum 198 characters per line
- F. Command set:
 - ASCII
 - space, backspace, carriage return, line feed, horizontal tab, form feed, end-of-text, acknowlegde, XON/XOFF
- G. Special Mode Commands:
 - Graphics mode, forward and backward print mode, program mode

for hammer intensity and ribbon movement

H. Weight and Dimensions:

	pounds	kilograms
1. Weight:	37.0	16.8
	inches	centimeters
2. Width:	23.22	59.0
3. Height:	6.87	17.5
4. Depth:	14.84	37.7

II. System Configuration

A. Lisa system

B. Apple III system

C. Apple IIe or Apple II Plus system

-- with Apple II Super Serial Interface Card installed

III. Features

A. Snap-in ribbon cartridge

B. Switch-selectable features:

- horizontal and vertical formatting
- forms length selection
- automatic form feed

HFS: Running applications under the Hierarchial File System

=====

Some applications have difficulty accessing their files when stored on an HFS volume. If an application has trouble finding files, try storing the files in one of the following locations:

1. root level
2. system folder
3. in the folder containing the application
4. on a MFS diskette/volume containing the application.

Some applications may not work with the HFS at all. In these cases, contact the software company to find out if there is a workaround or when their product will be revised to work with HFS.

HyperCard: Using It With Video Tape

Revised: 5/31/89
Security: Everyone

HyperCard: Using It With Video Tape

=====

This article last reviewed: 5 January 1988

HyperCard can be used for composing interactive videos by doing the following:

1. Use a high end VCR or VTR (3/4 inch tape) that allows you to accurately control tape position.
2. Record frame number information on a frame control track along with the video signal. If the VCR or VTR does not have this feature, HyperCard can not accurately control what is played from the video recorder.
3. Write your own custom HyperCard XCMD commands to control the VCR or VTR.

For further information on compatible VCR or VTR units, search under: Sony Corporation of America.

Apple IIC Numeric Keypad

Revised: 3/3/86
Security: Everyone

Apple IIC Numeric Keypad

=====

Apple makes no numeric keypad for the IIC, but Computers & More has developed an Apple IIC numeric keypad with 10 numerals, period, return(+), minus, tab, left arrow, right arrow, and down arrow. It is installable by any Tech, requiring no soldering and a case modification only if a disconnect plug is desired in the IIC. Retail is suggested at \$ 99.95 with customary margins. A disconnect kit is available for an additional \$ 20.00 . For information and availability contact:

Computers & More

Macintosh 512K: Problems installing new drivers on the HD20

Revised: 9/18/87
Security: Everyone

Macintosh 512K: Problems installing new drivers on the HD20

=====

This article last reviewed: 3 March 1986

When you use Installer to install new drivers on an HD20 using a Macintosh 512K, an error is generated ("File System not found on System Tools for..."). This problem may have its origin in HFS. There are three workarounds for it:

1. Drag a copy of the System Folder from the Tools Disk to update the HD20,
2. Move the System file outside of the System Folder when using Installer 2.0, or
3. Use Printer Installation v1.0, part number 690-5075-A.

NOTE: This problem has been fixed in the Macintosh Plus.

MacTerminal 2.0: Changes that affect 3278 emulation

Revised: 9/1/87
Security: Everyone

MacTerminal 2.0: Changes that affect 3278 emulation

=====

Following are some of the changes in Macterminal 2.0 that affect 3278 emulation:

1. 25th LINE: For status line. You need, of course, to re-configure your AppleLine.
2. NEW LINE: Now supported! The "Return" key is now NEW LINE. The "Enter" key retains its old function, ENTER.
3. NUMERIC KEYPAD: Remapped to include all 3278 keys--no numeric keys!
4. PASTE in PROFS: Now you can paste data into a PROFS file as well as any other IBM application that does not use line numbering. (Only through an AppleLine, though.) Pasting multi-line text selections into IBM 3278 documents with MacTerminal 1.1 caused ENTER to be sent after each line. This problem has been fixed.
5. RECORD SCREENS: More trap-conditions were added. You still can't see your ISPF screens, but at least in plain TSO you can LIST a file, and it'll be recorded.

NOTE: The selection box for Recording Screens appears under FILE TRANSFER!

6. CURSOR POSITIONING OVERRUN: If you work with a protocol converter that can't handle the big burst of characters sent on cursor positioning (up to 312 chars...), put some DELAY BETWEEN CHARS!
7. DELETE on Pull-Down Keypad: Now sends the right sequence ('7F'). There is no way to produce '1F'.
8. SHIFT-TAB for BackTab has been added.
9. APPLE CLUSTER CONTROLLER: Full support now exists for Pull-Down Keypad.
10. Increased throughput: This is probably more noticable at higher baud

rates, but MacTerminal 2.0 receives and displays characters about 1.5 times more quickly as version 1.1.

Additional MacTerminal 2.0 differences are documented in the Tech Info Library article entitled "MacTerminal 2.0: Differences."

ImageWriter II: Networking Options Available (1/96)

Revised: 1/30/96
Security: Everyone

ImageWriter II: Networking Options Available (1/96)

Article Created: 03 March 1986
Article Reviewed/Updated: 30 January 1996

TOPIC -----

This article describes the networking options available for the ImageWriter II Printer.

DISCUSSION -----

The LocalTalk option card for the ImageWriter II makes the ImageWriter II a shared resource on an AppleTalk network. The option lets you distinguish individual printers by assigning them unique names using the Namer accessory. If more than one printer of the same name resides on the same network, the option appends a number to the name.

Using the LocalTalk Bridge software, you can also tie your LocalTalk Option Card equipped ImageWriter II Printer to an Ethernet or Token Ring network -- eliminating the need to install a router or repeatedly switch network connections. The LocalTalk Bridge software uses a host computer as a bridge between the LocalTalk portion of a network and either Ethernet, or Token Ring portion of a network.

The Apple LocalTalk Bridge (M3246Z/A) comes with the LocalTalk Bridge software, installer, and User's Guide and has the following requirements:

- A Macintosh or Workgroup Server running Mac OS version 7.0 or later
- At least 70K of RAM
- An available LocalTalk port
- A LocalTalk connector and cable
- An Ethernet connection or Token Ring connection
- Appropriate network cables

Article Change History:
30 Jan 1996 - Corrected information on LocalTalk Bridge.

..TIL01774-ImageWriter_II-Networking_Options_Available_1-96_(TA33729).pdf

22 Jan 1996 - Revised the title to better reflect article contents.

07 Jul 1995 - Updated to include LaserWriter Bridge information.

Brother HR-15 Printer: Configuring it with an Apple IIC

Revised: 3/3/86
Security: Everyone

Brother HR-15 Printer: Configuring it with an Apple IIC

=====

The Brother HR15 printer requires +15 volts on several of its lines to accept data from the Apple IIC. This voltage is not available on any of the Apple IIC's serial port lines, so the existing cable for the Apple IIC does not work with the Brother HR15 printer.

Companies sell to dealers ready made cables that connect the Brother HR15 printer to the Apple IIC. One such company is Belkin Components (213-644-3184); they suggest a retail cost of \$24.95 for the cable.

If you wish to constuct your own cable, here are the pinouts:

Apple IIC	Brother printer
1	6,8
2	3
3	7
4	2
5	20
Shield	1
	4,5

The switches on the HR15 should be set as follows:

Switch 1 - Rear	Switch 2 - Rear
1-CLOSE	1-CLOSE
2-CLOSE	2-CLOSE
3-CLOSE	3-OPEN (read 8 bits, no parity)
4-CLOSE	4-CLOSE
5-CLOSE	5-CLOSE
6-CLOSE	6-CLOSE
7-CLOSE	7-CLOSE
8-CLOSE	8-CLOSE

The serial port on the Apple IIC should be configured as follows:

PIN 146/1111

Macintosh 512K: Using external 800K drives without a ROM upgrade

=====

Article Created: 3 March 1986
Article Last Reviewed: 31 March 1992
Article Last Updated: 31 March 1992

TOPIC -----

Will the external 800K drive work on a Macintosh 512K?

DISCUSSION -----

The external 800K drives will work on a Macintosh 512K that does NOT have a ROM upgrade. However, to use the external 800K drive with the Macintosh 512K, copy these three files:

1. System
2. Finder 5.1 or greater
3. Hard Disk 20

to your startup disk from the disk "Macintosh System Update for Macintosh 512K".

Macintosh Plus: Distribution of Features in System File and ROMs

=====

To distinguish between the contents of the new ROMs on the Macintosh Plus logic board and the contents of the new System file (3.0 and greater), keep in mind the locations of the following features:

New ROMs only:

1. HD 20 Driver
2. Zoom Box
3. HFS

Both new ROMs and new System file (3.0 and greater):

4. AppleTalk Driver
5. System Font
6. Serial Driver
7. Numerics Package
8. Elementary Functions Package

Features 4 through 8 are contained in BOTH the ROMs and the System file in order to maintain compatibility with the old ROMs.

Security: Everyone

Mini DIN-8: Serial pinouts for Hayes modems

=====

Article Created: 3 March 1986
Article Last Reviewed: 17 July 1992
Article Last Updated: 17 July 1992

TOPIC -----

What are the cable pinouts for a Macintosh Plus or later connected to a Hayes modem (Mini DIN-8 to DB-25)?

DISCUSSION -----

signal	dir- ection	Macintosh Plus & later		Hayes DCE connector	signal	dir- ection
		Mini	Circular DIN-8			
HSKo (DTR)	out	1		6	DSR	in
				20	DTR	in
HSKi (CTS)	in	2		8	DCD	out
				5	CTS	out
TxD-	out	3		2	TxD	out
Gnd		4		1	Gnd	
		8		7		
RxD-	in	5		3	RxD	in
		6				
		7				
					no connection	
					no connection	

Connect pins:

- 1. Macintosh side of cable: 4 and 8

2. Hayes side of cable:

- a. 6 and 20
- b. 8 and 5
- c. 1 and 7

The pins on the male end of the circular Mini DIN-8 connector are numbered as shown:

```
  6 7 8
 3 4   5
  1 2
```

You could also use the Apple II Printer - Mini DIN-8 Cable (part number 590-0556 or 590-0335), although the pinouts are slightly different.

Below are the pinouts for connecting the Hayes V series 9600 baud modems to the Macintosh with a DIN-8 serial port, direct from Hayes:

Hayes 9600 V	Macintosh
1-7	4-8
2	3
3	5
5	2
4	1

ProDOS Assembler EdAsm 1.1: Loading relocatable files

=====

Before you use ProDOS Assembler EdAsm 1.1 or 1.0 to load relocatable routine files, make sure the files are longer than 1K in code.

For example, the following program uses the files RBOOT and RLOAD under the ProDOS environment to load a relocatable routine file READBITS.0, file type REL, 87 bytes long:

```
10 AD=0
20 PRINT CHR$(4);"BRUN RBOOT"
30 AD=USR(0),"READBITS.0"
```

However, when the program runs, the error "No Buffers Available / Break in 30" occurs under BASIC.SYSTEM version 1.1, ProDOS version 1.1.1, and ProDOS EdAsm, release 1.0 dated 15-JAN-84.

To workaroud the problem, insert:

```
DS 1024,$EA
```

at the end of the program.

Macintosh Plus External 800K Disk Drive: Formatting environments

Revised: 9/18/87
Security: Everyone

Macintosh Plus External 800K Disk Drive: Formatting environments

=====

This article last reviewed: 3 March 1987

Whenever possible, you should update your application disks with the latest System and Finder files.

Below is a list of environments and the consequences for formatting, either in erasing or initializing.

1. Finder 4.1 with System less than 3.0

- a. Initializing: Does not initialize a blank diskette in either drive and displays the message "Init failed".

Using Finder 4.1 with System 2.0, we were able to initialize double-sided disks with no failures. This environment always formatted the disk as an 800K volume.

- b. Erasing: When you choose to erase, the Macintosh Plus erases a disk as an 800K volume, even if the disk was previously formatted as a 400K volume.

2. Finder 4.1 with System 3.0

- a. Initializing: Asks if you want single- or double-sided.
- b. Erasing: Only double-sided disks (800K)

2. Finder 5.1 with System 3.0

MacTerminal 2.0 VT-100 emulation: Functions on different keys

Revised: 9/1/87
Security: Everyone

MacTerminal 2.0 VT-100 emulation: Functions on different keys

=====

MacTerminal 2.0 uses different keys and combinations of keys for the VT-100 "Break" function on the Macintosh, Macintosh XL, and Macintosh Plus. The Macintosh and Macintosh XL have a main keyboard and a numeric key pad; the Macintosh Plus has a keyboard that performs differently.

Function:	Break	Enter	Long Break	Send Answerback Message
key or keys:				
on Macintosh OLD KEYBOARD	Enter	----	Shift Enter	Command Enter
OLD KEYPAD	----	Enter	----	----
on Macintosh XL KEYBOARD	Enter	Return	Shift, Option, Enter	Command Enter
XL KEYPAD	----	Enter	----	----
on Macintosh Plus KEYBOARD	Option Enter	Enter	Shift, Option Enter	Command, Option Enter
Function:	Break	Enter	Long Break	Send Answerback Message

Note: To use arrow keys on the pull-down or regular keypad, hold down the command key then click on or press the arrow key of your choice.

Inside Macintosh: Hardcover version missing a page

Revised: 5/10/89
Security: Everyone

Inside Macintosh: Hardcover version missing a page

=====

The hardcover, all-in-one Inside Macintosh manual from Addison Wesley is missing a page. Page 91 of Volume II was left out (containing a description of the FSOPEN File Manager call), and in it's place is Page 73 of Volume II (summary of OS Event Manager and data types). The page numbering is correct--it's just the page's contents that are wrong. So the manual contains two of the same page (pg. 73, vol. II), and none of another (pg. 91, vol. II).

Addison-Wesley is sending copies of the missing page to their bookstores for updating customers; we too will be receiving copies for distributing in our technical mailing. Permission has been granted to make as many copies of the errata as needed.

If someone insists upon receiving a corrected Inside Macintosh, refer them to Linda O'Brien at Addison-Wesley, (617) 944-3700, x2643, who will make arrangements for them to exchange their old copy.

Manzanita software: Using it on hard disks other than ProFile

Revised: 3/10/86
Security: Everyone

Manzanita software: Using it on hard disks other than ProFile

=====

To install The Advanced Business Accountant or BusinessWorks on a hard disk other than the Profile, the hard disk must be accessed before booting The Advanced Business Accountant Startup Diskette or the BusinessWorks BW.HARDDISK diskette. For example, if installing software on a Sider hard disk, boot the hard disk and select the ProDOS option and then select Basic. Insert the Startup diskette or BW.HARDDISK and enter PR#6 (or whatever slot the floppy disk drive is located in). Then follow the installation instructions provided. Once the software has been installed it may be selected by entering -TAB A for The Advanced Business Accountant or -BW for BusinessWorks at the Basic prompt.

Manzanita software payroll tax updates

Revised: 3/10/86
Security: Everyone

Manzanita software payroll tax updates

=====

This document provides a list of changes from the 1985 payroll tax tables to 1986 tables. The following list shows the status of federal and state tax tables in Manzanita Software Systems' Payroll modules for The Business Accountant, The Advanced Business Accountant and Payroll Plus. The first column lists the names of the states. Users should locate their state, then check the column to the right for the product they use. An "E" in the column indicates that changes have been made in that state's parameters and/or tax tables. The user should update his or her parameters and tax tables from the state-provided tax table information. An "*" in the column indicates that the state has changed calculation methods, so the user must get a Tax Table Update from Manzanita Software Systems. Without this update, payroll in that state will not calculate correctly. An "ok" in the column indicates that there have been no changes to the tables and no updating is required.

Users should also note that there are changes in the federal tax tables. All federal tax information can be changed by the user, with the exception of the earned income credit tables. If you have any employees who receive advanced earned income credit payments, then you must get a tax table update from MSS.

Tax Table updates are available for \$100.

Summary Report

As of: 2 / 27 / 86

Manzanita software: Printer Switch Settings

Revised: 3/10/86
Security: Everyone

Manzanita software: Printer Switch Settings

=====

The Business Accountant, The Advanced Business Accountant, and BusinessWorks require 10 characters per inch to properly align on preprinted forms.

Imagewriter:

	8	7	6	5	4	3	2	1	
Switch 1:				X					Closed
	X	X	X		X	X	X	X	Open

	4	3	2	1	
Switch 2:			X	X	Closed
	X	X			Open

Refer to page 40 and 41 of the Imagewriter Manual.

Imagewriter II:

Switch settings same as for Imagewriter. Be sure the perforation skip switch is off.

Interface Cards:

Grapler Plus: Must be version 3.2. To test for version, boot computer and enter PR#1 (be sure the printer is on and on-line). With the caps lock key on, enter Control-I V. The version of the card will print to the printer. Enter Control-I 80N for special character string in "Change Line Printer Configuration" option of System Setup and Configuration Menu.

ImageWriter: Spooling Available With QuickDraw GX (12/94)

Revised: 12/7/94
Security: Everyone

ImageWriter: Spooling Available With QuickDraw GX (12/94)

=====

Article Created: 5 January 1988
Article Reviewed/Updated: 7 December 1994

TOPIC -----

Is there a way to use background printing with an ImageWriter II printer?

DISCUSSION -----

With QuickDraw GX, you can use background printing on the entire ImageWriter series. This includes the ImageWriter, ImageWriter II, and ImageWriter LQ printers.

Non-QuickDraw GX printer drivers do not support background printing.

Article Change History:
07 Dec 1994 - Updated to include QuickDraw GX.
25 May 1994 - Updated with current information.

BASIC: Printing with properly aligned comma TABbing

Revised: 3/10/86
Security: Everyone

BASIC: Printing with properly aligned comma TABbing

=====

Applesoft BASIC comma formatting is only available for screen output. Comma formatting is not intended for printer output, and, with some combinations of a printer and its interface card, commas produce unwanted results such as misaligned fields.

To tab for printer output, use the command POKE 36,POS.

For example, these commands send the data in A, B, and C for printing in columns starting at 10, 30, and 50:

```
...  
100 POKE 36,10:PRINT A; : REM Go to column 10 and print A  
110 POKE 36,30:PRINT B; : REM Column 30, print B  
120 POKE 36,50:PRINT C : REM Last tab - no semicolon ends line
```

LaserWriter: Page counter is for maintenance only

=====

This article last reviewed: 10 March 1986

You can't reset the LaserWriter's page counter because it is part of the printer's firmware.

Use the page counter to determine:

1. when to change the toner cartridge (approximately 2,500 pages)
or
2. when to have routine service performed (approximately 100,000 pages).

I. Technical Specifications

A. Print Speed:

1. Letter mode: 50 cps at 10 cpi
2. Draft mode: 80 cps at 10 cpi
3. Speed selection
 - a. front-panel switch
 - b. software command

B. Print Method: Non-impact matrix printer

C. Character Format:

1. Letter Mode: 12(H) x 15(V) matrix alphanumeric and symbols
2. Draft Mode: 9(H) x 14(V) matrix alphanumeric and symbols
3. Superscripts/Subscripts: 9(H) x 14(V) matrix

D. Character Set:

1. 96 ASCII characters
2. 24 European characters

E. Character Pitch:

1. Letter mode: 10 cpi
2. Draft mode:
 - a. 10 cpi
 - b. 17 cpi

F. Line Spacing: 6 lpi (line per inch) plus n/144 in.

G. Line-Feed Rate:

1. 100 msec (at 6 lpi)
2. 180 msec for manual line feed

H. Graphics Densities: Variable

-- Maximum dots Per Lines: 1280

I. Resolution: Up to 160 by 144 dots per inch

J. Paper:

1. Width: 3.5 in. to 10 in. max
2. Thickness: .003 in. to .07 in. (equivalent to 15 to 25 bond)
3. Formats:
 - a. single cut sheet
 - b. fanfold continuous
 - c. paperback transparencies
 - d. mailing labels
- adjustable pin-feed tractors for labels
4. Supply: Compact paper supply tray fits under printer

K. Ribbon:

1. Type: single-pass, disposable cassette
2. Colors: black or three color
3. Life: 85,000 characters (average 40-50 pages)
4. Dimensions: 5/16 in. x 273 yd.

L. Interface:

1. Type: RS-232-C (serial)
2. Buffer: 1 line, current print mode
3. Baud Rate: 1200 or 9600
4. Apple systems:
 - a. Apple II
 - b. Apple II Plus
 - c. Apple IIe
 - d. Apple IIc

M. Electrical:

1. Input Power:
 - a. 115 V 60 Hz
 - b. 230 V 50 Hz
2. Power Consumption:
 - a. Standby: 20 Watts maximum
 - b. Printing: 60 Watts maximum

N. Physical Dimensions

1. Width: 14.5 in.
2. Height: 6.12 in. (with paper tray)
3. Depth: 12.4 in.
4. Weight: 14.1 lb.

O. Environmental:

1. Storage Temperatures: -4 to 104 degrees F (-20 to 40 degrees C)
2. Storage Humidity: 20 to 80%

II. Features:

- A. Cable and power cord connect to the side of the Scribe, well out of the paper path.

Macintosh Plus Upgrade: Removing The Security Kit

=====

Article Created: 10 March 1986
Article Last Reviewed: 24 July 1992
Article Last Updated: 31 March 1992

TOPIC -----

The following provides an explanation on removing the security kit from a Mac Plus.

DISCUSSION -----

Removing the security kit from the housing and keyboard is fairly simple once you've opened the case. From the inside of the case, merely pry the retaining prongs apart with a flatblade screwdriver and slip the plug out.

Applesoft BASIC: Displaying and printing text in 80 columns

Revised: 6/9/87
Security: Everyone

Applesoft BASIC: Displaying and printing text in 80 columns

=====

The Apple II permits input and output to only one device at a time, including the 80-Column Text Card in slot 3.

Here is a BASIC program that will send information to the printer, and then to the screen.

```
10 D$ = CHR$(4)
20 PRINT D$;"PR#1" : REM Turn on the printer in slot 1
30 PRINT "This sentence will be sent to the printer. Make it a long sentence,
so we can see if the printer uses 80 columns."
40 PRINT D$;"PR#3" : REM Turn off the printer; return to 80 column screen
50 PRINT "This sentence will appear on the screen."
60 END
```

If you find that the printer doesn't use 80 columns, then the interface card in the Apple IIe is set for 40 columns. Check the manual for that card, and change the DIP switches for 80 columns.

Use these techniques within any Applesoft BASIC program to turn a printer on and off, and still maintain disk drive access.

This short program shows how to print lines longer than 80 characters without overprinting. An explanation follows the listing.

```
10 D$=CHR$(4)
20 PRINT D$;"PR#1"
30 PRINT CHR$(9);"80N"
40 PRINT CHR$(9);"C"
50 LIST
60 S2$ = "We get a lot of calls regarding a problem with the Imagewriter I
and the Imagewriter II overprinting when using the PRINT command from
AppleSoft BASIC with lines that are longer than 80 characters. Here is a
workable solution."
70 PRINT D$;"PR#3"
```

In the statement `PRINT CHR$(9); "80N"`, (which sends Control-I 80N) the number

80 sets the printer card so that it sends a carriage return after sending 80 characters to the printer. The choice of the number, 60, 72, 80, or 132, to name a few options, depends on how you want to use the features of the printer and its interface card. This works for an Apple Super Serial Card, Apple Parallel Interface Card, and other popular interface cards.

After sending Control-I 80N to set the SSC to end its lines at 80 columns, it's still necessary to tell the SSC when that Control-I 80N command should work. That's what Control-I C does: it tells the SSC to issue a carriage return on column overflow.

Column overflow occurs when the SSC detects it has reached the end of the column as set by switches 2-3 and 2-4 or by Control-I 80N. The addition of a line like line 40 should correct similar overstriking problems, especially with listings of BASIC programs. If you run this program, it will correctly print S2\$ on an Imagewriter or an ImageWriter II.

On an Apple IIGS, the Control-I C would need to be a Control-I CE.

AppleWorks: Using it on the Apple II UniDisk 3.5

Revised: 3/10/86
Security: Everyone

AppleWorks: Using it on the Apple II UniDisk 3.5

=====

To catalog a disk in a Unidisk 3.5 on an Apple IIc with system utilities 2.1, you may choose 4 options on the menu screen:

1. built-in drive
2. external disk 3.5 #1
3. external disk IIc
4. Prodos Pathname

When choosing to format a disk, of course, the first 3 options are present.

Users of AppleWorks versions previous to version 1.3 may be confused by the menu screen shown when they choose to catalog a disk or change current disk:

1. Drive 1
2. Drive 2
3. Profile or other ProDOS directory

Choose option 3 to use the Unidisk 3.5 with AppleWorks before version 1.3. In these earlier versions, you can refer to the UniDisk 3.5 only by its pathname, such as /appleworks/business.

Refer to page 9 the pamphlet "Using AppleWorks on the Apple II Unidisk 3.5" for further explanations of how to load, save and list data files with Appleworks and the 3.5 disk.

Disk II: Connecting it to a Unidisk

Revised: 5/17/89
Security: Everyone

Disk II: Connecting it to a Unidisk

=====

To connect a Disk II to the back of a Unidisk, use a Unidisk cable, service part number 590-0327.

To install this cable on the Disk II:

1. Open the case of the Disk II
2. Pull out the old cable
3. Plug in the new cable.
4. File or drill a small half circle into the top of the case of the Disk II.
5. Reinstall the case, inserting the new cable into the half circle.

This modification should only be done by an Apple dealer, and will void the customers warranty.

The old and new cables are electrically the same; therefore, no other modification need be done.

To use a UniDisk on the Disk II controller card use a cable available from Quark, Inc., (303) 934-2211. Quark makes the cable to connect the Quark QC10 to the Apple IIc.

Instant Pascal: Transferring Programs to and from Mac Pascal

Revised: 3/10/86
Security: Everyone

Instant Pascal: Transferring Programs to and from Mac Pascal

=====

The Instant Pascal Master Program disk contains a file called "A2.TO.MAC." Use this file to transfer programs between a Macintosh and an Apple IIe or Apple IIc. A modem is not necessary.

Follow these steps, but first, if you have not already done so, delete some of the demonstration files from your master program disk before trying to use the file "A2.TO.MAC."

- A. Open the file "A2.TO.MAC" on the Master Program side of the disk.
- B. Print the file to a printer to obtain hard copy output.
- C. Enter the A2.TO.MAC program on your Macintosh using Macintosh Pascal.
Save the program.
- D. To set up an Apple IIe or Apple IIc to send files to a Macintosh:
 1. If you are sending files from an Apple IIe to a Macintosh:
 - a. Connect a Macintosh printer cable to the Super Serial Card installed in the Apple IIe.
 - b. On the Apple IIe, check to make sure the constants (CONST) are set at APPLE2C = FALSE and MAC = FALSE.
 - c. On the Macintosh, change the constant (CONST) default setting from MAC = FALSE to MAC = TRUE.
 - d. You must run A2.TO.MAC on both systems, beginning with the Apple IIe. Start A2.TO.MAC running on the Apple IIe BEFORE you start it running on the Macintosh.
 2. If you are sending files from an Apple IIc to a Macintosh:
 - a. Connect a female-to-female adapter to modem port of the Apple IIc.

- b. On the Apple IIc, change the constant (CONST) default setting from APPLE2C = FALSE to APPLE2C = TRUE.
- c. On the Macintosh, change the constant (CONST) default setting from MAC = FALSE to MAC = TRUE.
- d. You must run A2.TO.MAC on both systems, beginning with the Macintosh. Start A2.TO.MAC running on the Macintosh BEFORE you start it running on the Apple IIc.

E. A2.TO.MAC asks for the name of the file that you wish to transfer.

1. On your Apple IIe or IIc, either:

- Type in the file name and press Return
- or
- Select the appropriate box with your mouse and click the mouse button.

2. On your Macintosh:

- Type in the file name and select the appropriate box with your mouse and click the mouse button.

F. Check to see that the file you just transferred is actually on your disk.

This procedure is similar to that for transferring Macintosh Pascal files to Instant Pascal files and Apple IIe Instant Pascal files to Apple IIc Instant Pascal files. Read the instructions on A2.TO.MAC. Remember to run your Macintosh A2.TO.MAC program first.

ProDOS Access Unit: Volume not found error

Revised: 3/10/86
Security: Everyone

ProDOS Access Unit: Volume not found error

=====

The original release of SANE uses an early version of the ProDOS Access Unit. This version of the Access Unit checks the ProDOS disk for the version of ProDOS that formatted the disk, accepting versions of ProDOS equal to 1.0 or less. If the version on the ProDOS disk is greater than 1.0, such as 1.1.1, the Access Unit returns a 'volume not found' error.

For example, if you initialize a ProDOS disk using ProDOS V1.1.1 and then use SANE2 disk to build a custom FP library for ProDOS, the machine alternately:

1. reboots during the build
2. tries to access the disk after which the Access Unit returns a 'volume not found' error.

Workarounds

1. format the ProDOS disk from ProDOS 1.0

or

2. update to the latest version of the ProDOS Access Unit, available on SANE2 through Media Exchange.

Apple IIc Plus: How It's Different From The Apple IIc

Revised: 9/21/88
Security: Everyone

Apple IIc Plus: How It's Different From The Apple IIc

=====

This article last reviewed: 13 September 1988

Here are some of the new hardware changes in the Apple IIc Plus computer:

800K Internal Drive
Accelleration Circuit
Built-in Power Supply
Other Changes

800K Internal Drive

Support for the 800K internal drive is accomplished by a custom chip and dedicated RAM which interfaces with the IWM (intergrated Woz machine-disk controller chip) and the Apple 3.5" disk drive. The custom gate array is called the MIG (magic interface glue). A RAM buffer and the MIG are necessary to replace the circuit that is contained in the UniDisk 3.5 to provide support for the Apple 3.5" disk drive.

An additional 8K of ROM code was necessary to support the Apple 3.5" disk drive. The ROM does not provide support for copy-protection on the UniDisk 3.5" disk drive. There may be applications that used copy protection that worked on the UniDisk 3.5 but will fail on the Apple IIc Plus due to use of the Apple 3.5" disk drive.

Accelleration Circuit

New hardware has been added to the Apple IIc Plus to allow operation up to 4MHz. This circuit includes two 8K of static RAMs, a 65C02 running at 4MHz, and an 84-pin custom gate array to control access between the static RAM and the rest of the computer. The static RAM acts as a data cache for the 4MHz 65C02, and is controlled by the gate array.

Most programs run the same routines repeatedly. Using a cache is an ideal way of allowing these routines to be run faster, while letting the rest of the Apple IIC Plus continue at the normal 1MHz rate.

The gate array is the chip that enables the fast cache RAM method speed-up of the Apple IIC Plus computer. This chip is specific to the 65C02 and the Apple IIC Plus memory map. On one side of the gate array sits the 65C02 (4MHz) and two SRAMs for data cache. On the other side of the gate array is the rest of the Apple IIC Plus (video, I/O, memory, disk drive, ROM, etc.). The gate array knows which parts of Apple memory may be cached and which may not be (e.g. I/O), and keeps track of which bank of switched memory areas are switched in.

The cache RAM is transparent and not directly addressable. Data that fills the cache RAM can come from most areas of memory; main RAM, aux RAM, ROM, Language card RAM.

Built-in Power Supply

The Apple IIC Plus uses a built-in power supply to operate the computer. A battery power supply would have to provide the SUPPLY VOLTAGES. Due to the new design, an existing battery power supply for the Apple IIC will not work in the Apple IIC Plus. The internal power supply operates using the following parameters:

Electrical Requirements

- Line voltage: 90 to 130 volts AC
- Line frequency: 50 to 60 hertz
- Maximum power consumption: 20 watts continuous
- Supply voltages:
 - + 5 volts (+- 5%)
 - +12 volts (+-10%)
 - 12 volts (+-10%)
- Maximum supply currents:
 - + 5 volts = 1.5 amps
 - 5 volts = 30 milliamps
 - +12 volts = 0.9 amps continuous
 1.5 amps intermittent
 - 12 volts = 100 milliamps

Other Changes

There were a number of small changes to the Apple IIC Plus. These include:

- Volume Control slide located above the keyboard and replaces the 40/80 switch
- Rear handle locks in place
- Uses Apple standard mini-din 8 connectors
- Normal speed operation. (Hold down Esc key before you press Command-Control-Reset, Release the Reset Key, then release the ESC key when you see the word NORMAL on the screen, then release the other keys.)
- Headphone jack has been removed

Apple IIe: If Built-in Diagnostics Run on Power-Up

Revised: 7/24/92
Security: Everyone

Apple IIe: If Built-in Diagnostics Run on Power-Up

=====

Article Created: 11 March 1986
Article Last Reviewed: 17 July 1992
Article Last Updated: 17 July 1992

This article describes what to do if an Apple IIe's built-in diagnostics run when the system is powered on.

PROBLEM DESCRIPTION: When the Apple IIe is turned on, the system's built-in diagnostic program starts. (This program is normally initiated by pressing Control, Reset, Open Apple, and Closed Apple -- or by holding down Open Apple and Closed Apple at power on.) This is repeated until the system is powered off.

CAUSE: Keyboard or Keyboard Cable

BEFORE YOU START: Remove all peripheral cards from the Apple IIe to eliminate them as a possible problem.

CURE:

- 1) Remove any attached Joystick. The five buttons correspond to the Open Apple keys.
- 2) Verify that the keyboard cable is securely attached to the logic board and to the keyboard.
- 3) If the problem persists, replace the keyboard cable.
- 4) If the problem persists, replace the keyboard.
- 5) If the problem persists, refer to the Level I Technical Procedures.

To see a General Troubleshooting procedure, search on the product's name and HTS and GTS.

Apple III : Powers Up Into RAM/ROM Diag (But No Inverse 1s)

Revised: 1/17/92
Security: Everyone

Apple III : Powers Up Into RAM/ROM Diag (But No Inverse "1"s)

=====

Article Created: 11 March 1986
Article Last Reviewed: 17 July 1992
Article Last Updated:

BEFORE YOU START: Remove all peripherals cards from the Apple III to eliminate them as possible problem causes and boot the computer.

PROBLEM DESCRIPTION: The Apple III displays the Diagnostic RAM/ROM Test when booted. The RAM/ROM test is displayed as a Matrix of dots located at the upper left corner of the screen display. The Apple III will automatically display inverse "1"s (indicating bad memory chip/s) in the Diagnostic RAM/ROM Test if it has a "real" memory problem (which this problem isn't). With this problem, there are no inverse "1"s in the matrix of dots. If there are inverse "1"s, refer to the Tech Procedures for help in isolating the memory problem.

CAUSE: If inverse 1's are NOT displayed, the Apple III may have a keyboard problem or the power lamp may be burned out.

CURE: 1. Make sure that the keyboard is properly connected to the logic PCB.
2. If the keyboard is properly connected, check the power on lamp at the third key position from the lower left corner of the keyboard. If it is off, that is the problem so replace it.
3. If the lamp is OK, insert a boot disk into the internal drive and try to boot the system depressing just the Reset key.
4. If the system boots and seems to run normally, swap the keyboard.
5. If replacing the keyboard seems to cure the problem, try going go a step further and replace the Reset key.

If this cure does not resolve the problem, go back to the Word Search

screen and search on the product's name and HTS and GTS to obtain a General Troubleshooting procedure.

Apple IIe: Vertical Bars or Hissing after Logic PCB Replacement

=====

Article Created: 11 March 1986
Article Last Reviewed: 17 March 1992
Article Last Updated:

PROBLEM DESCRIPTION: After the logic PCB is replaced, the Apple IIe displays vertical bars on the monitor or makes a hissing sound.

CAUSE: The speaker wire may be shorting against the logic PCB.

- CURE:
1. Check to see if the speaker wire is running under the Logic Board. If this is the case the wire may have been punctured by one of the IC pins protruding from the bottom of the logic board.
 2. Route the wire over the top of the board and reconnect the speaker. If this cures the problem, replace the speaker with a new one.
 3. Follow the Level I Tech Procedures to replace the Logic Board.

If this cure does not resolve the problem, go back to the Word Search screen and search on the product's name and HTS and GTS to obtain a General Troubleshooting procedure.

Apple Iic : Logic PCB Bad After Iic Starts By Itself

Revised: 11/7/88
Security: Everyone

Apple Iic : Logic PCB Bad After Iic Starts By Itself

=====

Article Created: 11 March 1986
Article Last Reviewed: 17 July 1992
Article Last Updated:

PROBLEM DESCRIPTION: The system won't boot or exhibits diagnostic RAM failure after turning itself back on about 10 to 20 minutes after it was turned off.

NOTE: This usually occurred the first time the Apple Iic was turned and did not occur on all of the power supplies in the serial number range. Most of the power supplies in the serial number range work properly and will not show any of the described symptoms. If the Apple Iic is working properly there is no need to replace the power supply. All of the replacement module power supplies made by TDK have had this problem corrected. Refer to the Apple Iic Technical Procedures for more information on identifying reworked TDK power supplies.

CAUSE: Some TDK Apple Iic power supplies have a problem that causes them to turn back on spontaneously 10 - 20 minutes after the power switch has been turned "OFF". The power supply may have blown the RAM on the logic PCB when it turned itself back on.

CURE: To check for this problem locate the serial number/name plate on the power supply. Identify the vendor and date code for the power supply. The information on the plate is in the following order.

(Vendor)
699-0230
CE-0453
(Date Code)
(Serial Number) Japan

If the vendor is TDK, the power supply shows a date code between 8501 and 8526, and displays the problem stated above, replace the power supply and the logic PCB. Be sure to refer to the Apple Iic

Technical Procedures for complete information.

If this cure does not resolve the problem, go to the Technical Procedures to obtain a general troubleshooting procedure for this product.

ImageWriter II Paper Jams

Revised: 1/17/92
Security: Everyone

ImageWriter II Paper Jams

=====

This article last reviewed: 03 November 1987

PROBLEM DESCRIPTION: Paper jams or "paper folding" between the paper blade and paper bail assembly with the ImageWriter II.

BEFORE YOU START: There are four major reasons that paper jams occur with the ImageWriter II. Those are: a) the platen release lever is not in the correct position (released); b) possible obstruction(s) in the paper path (labels etc...); c) the paper has become deformed because of its being curved under the platen for an extended period of time; d) the paper guide is defective.

With most rear tractor feed printers it's not possible to just load the paper into the tractors and hit form feed to load the paper. You must guide the paper under the platen, then lock it into the tractors or use the procedure outlined in the IMAGEWRITER II owner's manual page 19. If this is the Problem reported, there isn't any 'fix', rear tractor feed printers don't do this gracefully.

CURE: Use the following procedures to troubleshoot the Problem:

1. Remove the paper from the printer and tear off the first page. Sometimes the first page of perforated paper is deformed from its being curved under the printer for an extended period of time (see Note 1). Reinsert the fresh paper and test the printer. Continue to the next step if the Problem still persists.
2. Check that the platen has been released from friction feed mode. Release the platen if the lever is in friction mode and test. Continue to Step 3 if the Problem still persists.
3. Check for the presence of obstructions in the paper path. One very common obstruction is that of a label that has adhered to the metal blade located under the platen. Clear any obstructions

and test the printer. Proceed to Step 4 if the problem persists.

4. Check the paper guide and make sure that it is not damaged. Sometimes the foil will peel from the plastic part of the paper guide assembly. Remove and replace the paper guide assembly if you find it to be defective. Proceed to the next steps if the problem persists.

4.A. Problem: The printer will print fine for several lines. Suddenly the carriage will stop and make grinding sounds. Home position is lost and the carriage crashes into either side of the printer. There is no error light.

Cure: Adjust the paper guide to be farther from the platen per Technical Procedures.

4.B. Problem: The paper jams in the printer and does not feed properly.

Cure: Adjust the paper guide to be farther from the platen per Technical Procedures.

Other causes for paper jams on the ImageWriter II.

5. Problem: The tractor assembly can be misaligned causing the paper to feed improperly.

Cure: Replace the tractor assembly

6. Problem: The paper out sensor is interfering with the paper path. You can really tell this when you insert a single sheet and the left hand side under the platen is 'tighter' than the right side.

Cure: Adjust the paper out sensor so it sits lower in the platen cradle, but high enough to detect paper out. To adjust the paper out sensor, take a screw driver and bend the sensor downward.

7. Problem: Paper bail is not aligned or one side is loose.

Cure: Adjust paper bail or replace

8. Problem: The metal plate on the left of the platen, which holds the platen in place on the left side is loose or out of adjustment (Technical Procedures, IMAGEWRITER II illustrated parts, page 6.36, part 'A')

Cure: Metal plate needs to be adjusted or tightened

Note 1: This step is listed first because deformity of the paper is quite common. Checking the friction lever is normally the first step performed when troubleshooting most other printers.

ImageWriter II: SheetFeeder Causes Top/Bottom Margin Problems

Revised: 11/10/88
Security: Everyone

ImageWriter II: SheetFeeder Causes Top/Bottom Margin Problems

=====

This article last reviewed: 10 March 1988

PROBLEM DESCRIPTION: The ImageWriter II SheetFeeder pulls the paper in about a 1/4" too much. The end result is a document that has a 1.25" margin at the top and a .25" margin at the bottom.

CAUSE: DIP switch set incorrectly

CURE: 1. Switch 5 on the ImageWriter II should be set to open.

Interpreting the Basic Lisa2/Macintosh XL Configuration Table

The top row (across) lists the system names for three basic configurations of the Lisa2/Macintosh XL. The first column (down) lists the names of basic hardware components. The YES or NO listed under each system indicates whether the hardware component is or is not a required part of that system. The "Notes" provide important information about software compatibility and hardware configuration for each system.

=====		

Interpreting the System Boards Compatibility Table

The top row (across) lists the system names for three basic configurations of Lisa 2/Macintosh XL. The first column (down) lists the names of the boards contained in the card cage and video chamber. The boxes under each system list the engineering numbers (printed near the edges of each board) and the Apple part numbers for each system board. The part numbers and rev. level for ROM on the CPU and I/O boards are included.

When inspecting or replacing system boards, use the System Boards Compatibility Table to make sure boards and ROM (part numbers and rev. level) match the information pertaining to the system you are working on.

NOTE: Any number can be in place of the "X" in the engineering numbers

listed on the table.

NOTE: Refer to the Module Identification Manual for pictures of the system boards.

LaserWriter Problem/Cure: New Cartridge Gives Lighter Print

Revised: 1/17/92
Security: Everyone

LaserWriter Problem/Cure: New Cartridge Gives Lighter Print

=====

This article last reviewed: 24 February 1988

PROBLEM DESCRIPTION: After a new toner cartridge is installed, the LaserWriter prints lighter than it did with the other toner cartridge.

CAUSE: The new toner cartridge's print may seem lighter, but it is actually still within specification. However see "CURE" below for the things you can do to improve print quality.

CURE: 1. Turn the Print Density dial located on the back of the printer, one graduation higher.
2. Make 100 to 200 copies to break in the toner cassette.
3. Return the Print Density dial to its normal range for the remaining life of the toner cartridge.
4. Make sure that the paper being used is 16 to 20 pound paper stock.

If this cure does not resolve the problem, the problem may be with the LaserWriter itself. Go to the LaserWriter Technical Procedures to obtain a general troubleshooting procedure for this product.

LaserWriter Problem/Cure: Only Prints Top Half of Page

Revised: 7/22/88
Security: Everyone

LaserWriter Problem/Cure: Only Prints Top Half of Page

=====

This article last reviewed: 20 July 1988

PROBLEM DESCRIPTION: The LaserWriter only prints the top half of the page.

CAUSE: A failed toner cartridge or DC Controller PCB.

CURE: Perform the User and Service Test prints to eliminate a failed I/O PCB as described in steps 1 and 2 of the LaserWriter Functional Check in the LaserWriter Technical Procedures.

If the problem is with the I/O PCB, follow the procedure located in the LaserWriter Technical Procedures to perform the repair.

If the problem is with the print engine replace the toner cartridge first and recheck for the problem. If the problem still remains, replace the DC controller PCB.

If this cure does not resolve the problem, go to the LaserWriter Technical Procedures to obtain the general troubleshooting procedure for this product.

400K Drive Problem/Cure: Fails to Read/Write or MacTest

Revised: 4/9/91
Security: Everyone

400K Drive Problem/Cure: Fails to Read/Write or MacTest

=====

This article last reviewed: 20 July 1988

PROBLEM DESCRIPTION: When running MacTest with a 400K drive the test says that the drive has failed.

CAUSE: Possible incompatibility between the drive and the boot ROM on the Macintosh. There are two revisions of stepper motors for the Macintosh 400K drive.

One of them, is compatible with any rev of ROM on the Macintosh.

The other is not compatible with revision A. It is only compatible with revisions B or later.

CURE:

1. Remove the drive case and examine the drive mechanism. Locate the label on the drive's stepper motor. If the label is circular and on the flat end of the stepper motor facing the rear of the drive, then the stepper motor is compatible with any rev of Macintosh boot ROM and if the drive fails MacTest, it should be replaced .
2. If the label is square and on the curved part of the stepper motor, then you need to check the ROM in the Macintosh to make sure it they are revision B or later. A square labelled stepper motor is not compatible with revision A ROM in the Macintosh. If the customer's Macintosh has revision A ROM installed, install revision B ROM to make it compatible with the disk drive.

If this cure does not solve the problem, go to the Technical Procedures to obtain a general troubleshooting procedure for this product.

Macintosh Problem/Cure: Sporadic Loss of Parameter Memory

Revised: 7/22/88
Security: Everyone

Macintosh Problem/Cure: Sporadic Loss of Parameter Memory

=====

This article last reviewed: 20 July 1988

PROBLEM DESCRIPTION: The problem Macintosh is at least 2 years old and begins to sporadically use the paramaters set into its parameter memory.

CAUSE: The Macintosh's battery is only designed to last two years and may be losing its charge.

CURE: Check the Macintosh's serial number for the below date information.

Typical serial number = F4325HR

F = Built in Fremont

4 = The last digit of the year built. In this case 84

32 = The week of production. In this case the 32nd week
in 1984

5HR = Information is not necessary for this article.

IMPORTANT: If you replace the battery, make sure that you record the date on a sticker or something. Then two years from the date you replaced the batteries, the troubleshooter will be able to determine the date when those batteries were installed.

If this cure does not resolve the problem, go back to the Word Search screen and search on the product's name and HTS and GTS to obtain a General Troubleshooting procedure.

Macintosh External Drives: Disks Only Insert About 1/2 in.

Revised: 8/20/92
Security: Everyone

Macintosh External Drives: Disks Only Insert About 1/2 in.

=====

This article last reviewed: 24 February 1988

PROBLEM DESCRIPTION: The disks will only insert about 1/2 inch and then stop.

CAUSE: The power may have been turned off during the eject cycle or a paper clip may have been used to eject the disk and was not pushed in far enough for the cycle to be completed.

CURE: On the front of the drive, there is a little hole to the lower right of the disk entrance. Insert a paper-clip firmly into this hole and hold it until the eject cycle is completed

If this cure does not resolve the problem, follow the recommended Apple repair policy for this product.

Macintosh: Cure for Wrong System Font

=====

Article Created: 11 March 1986
Article Last Reviewed: 17 July 1992
Article Last Updated: 17 July 1992

PROBLEM DESCRIPTION: Some applications occasionally cause desktop icons and window information to be displayed in the wrong system font. The same disks work fine on other Macintoshes. Turning the Macintosh off then back on again does not usually clear the problem.

CAUSE: Parameter memory contains the wrong information.

CURE: For 128K, 512K, 512Ke, or Plus unplug the Macintosh and remove its battery for 15 seconds or so. This will clear the Macintosh's parameter RAM.

For NuBus or System 7 Macintosh, hold down Command-option-R-P until the system sounds the startup chord a second time. Release the keys.

For SE or SE/30, hold down Command-option-shift and open the control panel. Release the keys and acknowledge any dialog boxes.

Finally, reset the Control Panel settings.

Disk III P/C: Calibration Using an Apple IIe

=====

This article last reviewed: 24 February 1988

BEFORE YOU START: Read the Disk II Adjustment and Calibration sections in the Tech Procedures.

PROBLEM DESCRIPTION: Drive exhibits problem(s) that you think can be attributed to improper adjustment or calibration.

CAUSE: You may not have an Apple III or III+ available to adjust and calibrate the Disk III.

CURE: 1. Remove and replace the Disk III analog card with a Disk II analog card.
2. Attach the Disk II analog card to the Disk III's controller card with the Disk II's analog card to controller card cable
3. Perform the adjustment and/or calibration procedures as described in the Tech Procedures for Disk II.

If the above cure doesn't fix the problem, search on GTS and the product's name to obtain a general troubleshooting procedure.

Macintosh XL: Screen Kit Notes

Revised: 9/30/88
Security: Everyone

Macintosh XL: Screen Kit Notes

=====

This article last reviewed: 31 August 1987

1. The Macintosh XL Screen Kit alters the video display of a Macintosh XL (Lisa 2/10 or Lisa 2) so that the video display pixels are square (as on the Macintosh screen) as opposed to the pixel ratio on the Lisa (2 units wide by 3 units tall). This eliminates the distortion experienced by XL users when running Macintosh software under MacWorks XL. The video display is changed from 720 x 364 to 608 x 431 pixels.

2. The kit contains 4 components:

1 transformer	installed in line with the yoke of the CRT (yellow and green wires)
---------------	---

Video State ROM	P/N 341-0348	installed in location C 6 (CPU Board)
Boot ROM (High)	P/N 341-0347	installed in location D 13 (CPU Board)
Boot ROM (Low)	P/N 341-0346	installed in location D 14 (CPU Board)

3. The version of the boot ROM that is displayed in the upper left corner of the XL while booting is 3A. On an XL the I/O ROM is still 88; on the Lisa 2 the I/O ROM is A8.

4. A new version of Mac XL Test, P/N 077-0206 is required to run diagnostics on a pixel modified Macintosh XL. Earlier versions of XL Test will not run properly on a modified XL.

5. A full screen dump on a Macintosh XL still wraps the right part of the screen around to the left side of the printer page, but due to the reduced number of pixels horizontally, 720 vs. 608, the printing does not actually overwrite the left side of the screen dump.

6. The pixel fix kit greatly improves the performance of Microsoft Chart. The printed graph does not show up in unexpected locations on the printed copy after it looked perfect on the screen of your XL.

7. Very important: Once the pixel fix kit is installed, the customer will be unable to run Lisa software. Since the first part of the Lisa-to-Mac migration is run under the Lisa Office System, which cannot be done on a system that has been modified with the Screen Kit, install the pixel fix after you use the migration utility to transfer your Lisa software to the Macintosh environment.

General Information on Northern Telecom's LANStar/PTE

Revised: 12/6/89
Security: Everyone

General Information on Northern Telecom's LANStar/PTE

=====

This article last reviewed: 15 February 1988

Northern Telecom's LANStar technology is based on the data handling capabilities of a central "frame" known as the packet transport equipment (PTE). The standard PTE resembles a full-height rack-mount frame in which earlier DEC minicomputers were mounted. It is divided into "shelves" and each shelf contains slots or tracks into which "modules" can be inserted.

Northern Telecom makes several different sorts of modules for this frame, most of which have nothing to do with LANs, but are related to voice processing, i.e., voice messaging, etc. One LANLink assembly, made up of two cards, is the basis for the local area networking capabilities of the PTE. Each assembly supports 16 nodes through the PTE. There are currently two versions of the PTE. The large one, known simply as the PTE, addresses 1,344 nodes. A smaller one, the PTE/S, can address 112 nodes. The smaller PTE can support ONLY the LAN modules, and not the other voice processing modules available for the large frame.

Communications between the PTE and the desktop workstation is via two twisted pairs (four wires). If the wiring must also support voice, a third twisted pair is required. Thus, buildings wired with at least three pair to each desktop are best suited for LANStar technology. Of course, there is a LANStar card in the desktop works MS-DOS based PCs (traditional slots, not MicroChannel). Data transfer between the workstation LAN card and the LANLink card in the PTE is at 2.56 Mbps. There is absolutely no contention for this 2.56 Mbps bandwidth, as there is only one workstation attached to each PTE-LANLINK card. It appears from some of the materials available that this communications may be full duplex.

Back at the PTE, each PTE LANLINK card is plugged into a backplane bus. The PTE LANLINK cards communicate between themselves at 40Mbps, 8 bits wide. Obviously, as there could be 1,344 cards wanting to talk at 2.56 Mbps all at once, and 40 Mbps won't go around, there must be some "link access protocol managing access" to the 40 Mbps bus. This is where the telephone heritage of the PTE shows through. Rather than using CSMA/CA, CSMA/CD, or token passing,

the PTE bus uses a form of time division multiplexing that Northern Telecom calls "Perfect Scheduling". The 40 Mbps bandwidth is divided into time slices during which certain sorts of tasks are allocated/guaranteed bandwidth. This time slicing is controlled externally to the data bus. There is virtually no bandwidth consumed by link access overhead, even under very heavy loads.

In some ways, this access scheme is similar to token passing, in that a given data transmission will have to wait its turn for bus access. But unlike token rings, a LANLink card failure cannot result in loss of the token. And no data bus time is consumed in simply passing the token around. The bandwidth is also sliced very fine: 8,000 slices per second, with 640 frames per slice (each frame carries 8 bits), so the wait should never be long.

As already stated, the PTE is wired as a star: a separate set of twisted pair goes from each workstation back to a corresponding LANLink card in the PTE. However, within the PTE the network takes on a more bus-link structure. Billed as one of LANStar's security features, packet address interpretation is all done inside the PTE bus, with each PTE LANLink recognizing its own address (note that the address, at least at this level, is the address of the PTE LANLink card, not the address of the LANStar card or the workstation itself) and capturing ONLY packets intended for it. Thus, anyone tapping into a leg of the star will see ONLY the data traffic for the workstation attached to that leg - not any of the traffic for any of the other legs. Broadcasts, of course, still go to all legs.

The PTE LANStar technology is also available to the MS-DOS world. The LANLink PC card goes in a standard MS-DOS slot, and connects to the same PTE equipment as is used with LANStar AppleTalk. In the Macintosh world, LANStar AppleTalk has (separately) been tested with MacServe, TOPS, and AppleShare. In the MS-DOS world, LANStar is in use with MS-Net and Banyan's Vines/286 servers.

It appears possible to attach both Macintoshes and MS-DOS PCs to a single PTE LAN. However, similar to running multiple protocols over Ethernet, the Macintoshes and their AppleShare will not see the PCs and their MSNet, etc. AppleShare PC, TOPS for PC, or Tangent Share do not solve this problem, because they all require an AppleTalk board for the MS-DOS PC -- not a PC LANLink card. Initial testing of this multiple protocol PTE LAN seems to run well. Apparently there is some performance degradation on the MS-DOS side, having to do with the number of broadcast packets used by AFP, vs. the number of broadcast packets expected by the Vines/286 server. The problem is not severe, as it was detected only through use of performance monitoring tools on the network.

Bridging between the different protocols seems to be the best possibility for a mixed MS-DOS-Macintosh LANStar network. At least one of the MS-DOS PCs could run both TOPS and LANLINK and republish volumes as a gateway. Or, when the LANStar Bridge becomes available, PCs running an AFP based network could bridge onto a LANStar AppleTalk network to get to an AFP server. Long term, some further integration between MSNet based networks and AFP networks would be desirable.

Apple IIGS: Hard Drive Speed is Limited by System Speed

Revised: 1/20/88
Security: Everyone

Apple IIGS: Hard Drive Speed is Limited by System Speed

=====

This article last reviewed: 6 January 1988

Will a 29ms hard drive perform twice as fast as a 65ms hard drive if both are run on an Apple IIGS with the Apple SCSI card? In other words, is the hard drive the slower component, or the Apple IIGS with the Apple SCSI card?

The maximum data transfer rate for the SCSI bus is 1.25 MBytes per second. If the disk accesses the data faster than that, it is not apparent to the user. The determining factor for data transfer is system overhead. In this case, the system is the slower component.

System overhead consists of: operating system timings, interface timings, and the interleave factor for the disk (which is 3 to 1 for the Apple IIGS). If the 65ms drive is waiting for the Apple IIGS system, then changing to a 29ms drive will probably not increase performance.

IBM PC: How to use the LaserWriter with it

=====

This article last reviewed: 19 March 1986

Serial Port (for software that supports PostScript)

1. Begin by detaching all connections to the LaserWriter and make sure the LaserWriter has been turned off.
2. Take your null modem cable and connect one end to the 25 pin plug on the LaserWriter and the other end to the RS232 serial port on the IBM .
3. Look for the switch on the LaserWriter and set it to 9600.
4. Turn on the LaserWriter.
5. Wait for the test page to eject, then follow the instructions for you application. (See Note)

Diablo 630 Emulation (for software that does not support PostScript)

1. Begin by detaching all connecions to the LaserWriter and make sure the LaserWriter has been turned off.
2. Take your null modem cable and connect one end to the 25 pin plug on the LaserWriter and the other end to the RS232 serial port on the IBM.
3. Look for the switch on the LaserWriter and set it to Special.
4. Turn on the LaserWriter.

The connections have been made and you may now set up the software package to the Diablo printer driver. No test page will appear. (See Note.)

AppleTalk PC MacBridge Tangent Technology Card

1. Begin by placing the Tangent Technology card in an available slot.
2. Connect the AppleTalk cables to the Tangent port on the IBM and to the AppleTalk connection on the LaserWriter.
3. Look for the switch and set it to AppleTalk.
4. Turn on the LaserWriter.
5. Wait for the test page to eject, then follow the MacBridge menu instructions for communications.

NOTE: These DOS commands must be executed before using the LaserWriter from the serial port. (They may be included in a batch file for ease of execution.) The DOS file MODE.COM must also be on the disk for these commands to work properly.

```
MODE COM1:9600,N,8,1,P
MODE LPT1:=COM1:
```

Applications that do not support Xon/Xoff communication protocol may have problems with large files.

Macintosh Plus: Using Microsoft applications on an 800K disk

Revised: 2/11/88
Security: Everyone

Macintosh Plus: Using Microsoft applications on an 800K disk

=====

This article last reviewed: 21 April 1986

With the release of the Mac+ and double sided disk drives, many people will want to put Microsoft applications on 800K disks. The following information will take you through the steps needed to prepare an 800K disk for use with Microsoft applications.

The following information assumes that you already know how to perform basic operations with your Apple Macintosh. You should know how to use the Finder and the mouse, eject disks, and copy files. If you are not familiar with these operations, please refer to your Macintosh users manual. The following steps assume you are using a Mac+ with an 800K external disk drive.

1. Start the computer with the system disk that came with your computer. This system disk should contain a system file (v3.0 or higher), and a Finder (v5.1 or higher).
2. Insert a blank disk into the external disk drive and initialize it to be an 800K disk.
3. Copy the system folder from the Mac+ system disk to the initialized 800K disk.
4. Now eject the system disk from the internal disk drive and insert the Microsoft application disk. (If you are setting this disk up for Microsoft Excel, insert the program disk marked 1 of 2).
5. Copy the program and any other files such as printer drivers, help files etc., to the newly formatted 800K disk in the external disk drive. DO NOT COPY THE SYSTEM FOLDER. You have already copied the system folder from the Mac+ system disk.

The process is now complete. You may shut down and reboot the computer with the 800K disk that you just prepared. When you start one of our applications, the program will start to load and then ask for the master. You will have to

insert the master once when you start the program.

SETUP FOR 512K MAC AND 800K EXTERNAL DISK DRIVE

The following steps will allow you to set up your 800K disks with Microsoft applications to run on a 512K mac.

1. Start the computer by inserting the new system disk into the internal drive. The system disk must be on a 400K disk and contain a system file (v3.0 or higher), Finder (v5.1 or higher), and an HD 20 file.
2. Insert a blank disk into the external 800K disk drive and initialize it for 800K.
3. Make a copy of the system folder (containing the system, Finder, and HD20 files) onto the 800K disk in the external disk drive.
4. Now eject the system disk from the internal disk drive and insert the Microsoft application disk. (If you are setting this disk up for Microsoft Excel, insert the program disk marked 1 of 2).
5. Copy the program and any other files such as printer drivers, help files etc. to the newly formatted 800K disk in the external disk drive. DO NOT COPY THE SYSTEM FOLDER. You have already copied the system folder from the Mac+ system disk.

The process is now complete. When using a 512K mac with 800K external disk drive, you must always start the computer with the 400K system disk, containing the system, Finder, and HD20 files) in the internal disk drive. Insert the newly prepared 800K application disk into the external drive and start the application. The system disk in the internal drive will be ejected and the program will ask for the master. After you insert the master, it will be ejected and the internal drive will be free. You will be able to save data files to the internal drive.

Multiplan: Beware when loading files from a nearly full disk

=====

This article last reviewed: 21 April 1986

In Multiplan 1.02, 1.01 and 1.0, if you load a file from a nearly full disk and add enough that it will not fit on the disk, you will get a disk full message when you try to save. You will also lose the original copy on the disk.

What plan does during saving is first erase the old copy, then tries to save the new version. Just use "Save As ..." and save to another disk before quitting. Otherwise you will lose both copies of the file.

Multiplan 1.02, 1.01 and 1.0: Saving large clipboard

Revised: 2/11/88
Security: Everyone

Multiplan 1.02, 1.01 and 1.0: Saving large clipboard

=====

This article last reviewed: 21 April 1986

The "saving large clipboard" dialog comes up any time you have more than 50 cells in the clipboard. If you have more than 100, both the check boxes are off, otherwise both are on. You never get one off and one on. If you save Formatted, you get a TEXT scrap--complete with dollar signs, etc. If you save unformatted you get a value scrap--the raw numbers to the best accuracy plan can produce (for pasting to Chart or BASIC).

When running Multiplan and EXCEL through the Switcher, you must select a large enough area to get this dialog box in order to get the information into the clipboard and copy it to Excel. Otherwise it will not enter the clipboard when you switch applications.

Multiplan 1.02, 1.01 and 1.0: Inserting a row

Revised: 2/11/88
Security: Everyone

Multiplan 1.02, 1.01 and 1.0: Inserting a row

=====

This article last reviewed: 21 April 1986

Q. I am trying to insert a row with Multiplan and it doesn't insert. Why?

A. When you select the last cell (from the Select menu), and the selected cell ends up being in row 255, Multiplan thinks you are using this entire area and that there are no more rows to insert. Select all rows (by pointing to the row numbers) beyond the actual working area of the document and use the Cut command to remove them. You will then be able to insert rows. This is most commonly caused by formatting entire columns rather than just the cells used.

Macintosh XL: Incompatible With System 4.0 & ImageWriter LQ

Revised: 11/22/91
Security: Everyone

Macintosh XL: Incompatible With System 4.0 & ImageWriter LQ

=====

This article last reviewed: 6 January 1988

People have asked if Macintosh XL can run on System 4.0, and if it can use System 4.0 to run an ImageWriter LQ.

The Macintosh XL was officially discontinued on May 1, 1986, and there is no new hardware or software development (including system software) for the Macintosh XL. Software and hardware support will continue for five years from the date the machine was discontinued.

At the time of the Macintosh XL discontinuation, the System software was System 3.2 and Finder 5.3. This software contained patches that allowed it to run on a Macintosh XL. Any System software released AFTER these versions does not contain the necessary patches to run properly on the Macintosh XL.

The ImageWriter LQ must use current versions of the System file (version 4.1 or later), Finder (version 5.5 or later), and Chooser (version 3.1 or later) with ImageWriter LQ printer resources, so ImageWriter LQ should not be used with a Macintosh XL.

For further information on enhancements for Macintosh XL, search under: Sun Remarketing

LaserShare 1.0: Error Can Result From Changing Long Spooler Name

=====

This article last reviewed: 7 January 1988

A system error can occur on LaserShare 1.0 when a very long spooler name is changed.

If the user has a multi-zone network, with multiple LaserWriters in each zone, when starting LaserShare and capturing the printer, LaserShare will show a system error (ID=02) when the user tries to alter the default spooler name provided in the dialog box.

In this example:

Zone name = INFO. SERVICES

Laser name = LASERWRITER PLUS- SOUTH

the generated name is

LASERWRITER PLUS- SOUTH INFO. SERVICES...SPOOLER (48 characters)

which runs out the end of the text box. If the user tries to type a shorter name, LaserShare crashes.

ImageWriter LQ: Transparencies Cause Optical Sensor Problems

Revised: 1/20/88
Security: Everyone

ImageWriter LQ: Transparencies Cause Optical Sensor Problems

=====

This article last reviewed: 7 January 1988

The ImageWriter LQ does not recognize unbacked transparency material, due to its optical paper sensor.

Optical sensors are normally of two types: see-through and reflective. Both have difficulty detecting transparencies.

- Reflective sensors depend on a certain amount of light being bounced back to the sensor by reflection from the paper. If that amount is not received, the sensor believes there is no paper in the printer.
- See-through sensors depend on seeing little or no light through the paper. Because transparency material passes too much light, the sensor doesn't detect paper.

Transparency material that has a white backing sheet is available, and can be used in the ImageWriter LQ or ImageWriter II. The image density isn't significantly greater on the Imagewriter LQ than on the ImageWriter II, since the print density on transparency material is very weak no matter what printer is used -- the surface is generally too smooth to accept much ink from the ribbon.

Microsoft Word: Recovering Documents After a Crash

=====

This article last reviewed: 9 December 1987

If your system crashes while Microsoft Word is running, documents that were open at the time of the crash can be recovered.

When you restart after the crash, you should find one or more Word temporary files on your disk (probably in the System folder). The names of these files have the form:

- MWnnn (Word 1.0 or 1.05), or
- Word Temp n (Word 3.0)

Word can't read these temporary files until you use a utility program to change the temporary file's file type from WTMP to WDBN. Here's how to use FEDIT PLUS to make the change:

1. Make a backup copy of the temporary file. Just in case.
2. Start FEDIT PLUS.
3. Select Open File from the File menu.
4. Open the temporary file.
5. Select Display Sector in Hex from the Display menu.
6. Select File Finder Attributes from the Display menu.
7. The File Type field is highlighted (it's probably WTMP). Type WDBN then click Change.
8. To confirm the change, close all windows. Start again at step 3 and see if the file type is now WDBN.

9. Click Cancel; Quit FEDIT PLUS.

Word should now be able to open the file. Changes made since the last time you saved won't be there, but the file should be complete otherwise.

ImageWriter II: Auto-skipping the perforation

Revised: 4/21/86
Security: Everyone

ImageWriter II: Auto-skipping the perforation

=====

There are two ways to automatically skip the page perforation on the ImageWriter II. The first way turns auto perforation skip off and on for a standard size page:

--To turn auto perforation skip on, type:

```
PRINT CHR$(27);"Z";CHR$(0);CHR$(4)
```

--To turn it off, type:

```
PRINT CHR$(27);"D";CHR$(0);CHR$(4)
```

The second way affords you the benefit of being able to place the auto perforation skip anywhere you wish, allowing you to use shorter paper. For instance, if you have a nine-line page and wish the ImageWriter to print seven lines and then skip two, you would type:

```
PRINT CHR$(29);"A@@@@@@@@@C@@@@A@";CHR(30)
```

This second, more powerful way is described in seven pages of the ImageWriter II technical reference manual.

NOTE: The second method also works for the regular ImageWriter.

Scrapbook: In Finder 5.1 Scrolls Slowly Between Items

=====

Article Created: 21 April 1986
Article Last Reviewed: 27 May 1992
Article Last Updated: 27 May 1992

While in Finder 5.1 (at the Desktop), the Scrapbook may take a long time to scroll from item to item. This happens because the Scrapbook looks through ALL available open resources as it scrolls. When the system is at the Finder level, there are many open resources. This behavior is not exhibited from within most applications since most applications keep fewer resources open.

IEEE-488 Interface Card: Internal Cable Pinouts (11/96)

Article Created: 21 April 1996
Article Reviewed/Updated: 14 November 1996

TOPIC -----

Listed below are the pinouts for the IEEE cable.

DISCUSSION -----

As both connectors are mass terminate type connectors, the pinouts are straight through, with the following exceptions:

Card 26-pin internal connector	24-pin external connector
pin	pin
12 no connection	12 separate ground *
25 no connection	
26 no connection	

* Grounding occurs with a special connection to pin 12 on the external connector. This special wire leads from pin 12 on the external connector to system or chassis ground as pictured on page 6 of the IEEE card manual. The wire must NOT be connected to the ground signal of the card or the slot.

Duodisk Problem/Cure: Won't Format-Says "Volume Not On Line"

=====

This article last reviewed: 10 March 1988

PROBLEM DESCRIPTION: When trying to format a brand new disk, i.e. one that has never been formatted , the system returns a "Volume Not On Line" error prompt. Other error prompts may occur depending on the application you are using to format the disk.

CAUSE: The revision of the Format Utility that is being used may be incompatable with the Analog PCB in the DuoDisk.

CURE: Use revision 2.1 or newer of the System Utilities. If the format attempt fails again, swap the analog PCB and retry.

If the above cure doesn't fix the problem, search on GTS and the product's name to obtain a general troubleshooting procedure.

Macintosh Plus P/C: No Response From Apple Personal Modem

Revised: 1/17/92
Security: Everyone

Macintosh Plus P/C: No Response From Apple Personal Modem

=====

This article last reviewed: 10 March 1988

PROBLEM DESCRIPTION: When using the old MacTerminal program with the Macintosh Plus and the Apple Personal Modem, there is no response from the modem.

CAUSE: The Data Terminal Ready (DTR) signal is not activated from the old serial driver. This signal would normally be used by the Macintosh to let the modem know that it is activated. Without DTR the modem will not look at any other signals from the Macintosh.

CURE: Use MacTerminal 2.0 with the new system and finder because it will activate the DTR signal on the Macintosh Plus.

If the above cure doesn't fix the problem, refer to the Tech Procedures for this product's troubleshooting procedure.

Apple IIC Prob/Cure: Data Errors When Sending to Serial Device

=====

This article last reviewed: 10 March 1988

PROBLEM DESCRIPTION: Data errors occur when the Apple IIC transmits data to a serial device (modem, printer, etc.).

CAUSE: There may be a timing problem in the Apple IIC motherboard.

CURE: Check location UC7 on the motherboard for a "black" (not silver) LS161 integrated circuit. If this component is black, then this board has a timing problem so the motherboard should be replaced. Refer to the service programs binder to see if the repair can be reimbursed under a special warranty program.

If the component is silver, then the board does not have the timing problem.

If the above cure doesn't fix the problem, search on GTS and the product's name to obtain a general troubleshooting procedure.

ImageWriter: Print Fades Intermittently

Revised: 1/17/92
Security: Everyone

ImageWriter: Print Fades Intermittently

=====

This article last reviewed: 10 March 1988

PROBLEM DESCRIPTION: Printing is fine most of the time, then the print will fade. After a space of 15 or so characters, the print density returns. The location of the print fade can happen anywhere on the document.

CAUSE 1: If the ribbon cartridge may not be a genuine Apple cartridge, the ribbon may fit loosely in the ribbon mechanism. This causes the clutch on the ribbon to slip when it turns to advance the ribbon.

FIX: Replace third party ribbon with a genuine Apple ribbon.

CAUSE 2: The ribbon may be catching on the screw which fastens the paperguide in place.

FIX: Tighten or replace the screw as appropriate.

CAUSE 3: The springs part numbers 970-0063 and 970-0064 may be misplaced. These springs have different tensions. Spring 970-0063 is the one with a greater tension. When misplaced it will cause the gear 970-0061 to slip.

FIX: Check the tension of the springs and install them in their proper place. After repair, reinstall all the parts in the carriage and run Self Test to check for proper operation of the printer.

If the above cure doesn't fix the problem, search on GTS and the product's name to obtain a general troubleshooting procedure.

ImageWriter 15 Problem/Cure: Prints OK But Makes Grinding Sound

Revised: 1/17/92
Security: Everyone

ImageWriter 15 Problem/Cure: Prints OK But Makes Grinding Sound

=====

This article last reviewed: 10 March 1988

PROBLEM DESCRIPTION: ImageWriter 15" prints OK but the carriage seems to make a grinding sound when moving across the print bar. This often happens after the carriage motor has been replaced.

CAUSE: The screws mounting the carrier motor on its grommets may be too tight causing vibration (grinding noise).

CURE:

1. Loosen the screws that secure the Carrier Motor Clamps.
2. Loosen the four screws that secure the Carrier Motor to the bottom cover of the printer.
3. Cross tighten the four Carrier Motor Screws until you feel some resistance but DO NOT over tighten. If the Carrier Motor has just been replaced and the screws have been over tightened, you may have to replace all eight Carrier Motor Rubber Grommets and cross tighten again. Remember, tightening the screws to much will cause the grommets to over compress and cause a vibration that exhibits the grinding sound.
4. Tighten the screws that hold the Carrier Motor Clamps.
5. Run Self Test to check for the vibration problem.

Note: You may have to follow the above procedure several times before the noise is eliminated.

If the above cure doesn't fix the problem, search on GTS and the product's name to obtain a general troubleshooting procedure.

ImageWriter II Problem/Cure: Ink Spots or Streaks

Revised: 1/17/92
Security: Everyone

ImageWriter II Problem/Cure: Ink Spots or Streaks

=====

This article last reviewed: 10 March 1988

PROBLEM DESCRIPTION: The Imagewriter II leaves ink streaks or spots on the paper as it prints. These streaks may be light or dark, and resemble smudges. Leaving the printer idle for a period of time with a piece of paper in it may leave a spot on the paper when it is advanced out of the printer.

CAUSE: Customer may have forgotten to set the paper thickness lever to the proper thickness when printing on an envelope or multiple pages. This causes the metal part of the paper guide to press against the ribbon cloth during printing which 'scrapes' some of the ink off of the ribbon and deposits it on the guide. If enough ink builds up, it will begin to smear onto following pages.

CURE: Remove the paper guide from the carriage assembly using the procedures outlined in the Tech Procedures. The metal shield on this part will probably be coated with a layer of ink (possibly thick). Use isopropyl alcohol to thoroughly remove the ink. Be careful not to bend the metal shield. Re-install shield as close to the platen as possible. This will put the ribbon a little farther from the paper guide helping to prevent ink from building up. Advise the customer to prevent this problem, he/she should adjust for proper paper thickness when printing on envelopes and multiple pieces of paper.

If the above cure doesn't fix the problem, search on GTS and the product's name to obtain a general troubleshooting procedure.

ImageWriter I Problem/Cure: Single Sheet Paper Skews

Revised: 4/26/89
Security: Everyone

ImageWriter I Problem/Cure: Single Sheet Paper Skews

=====

This article last reviewed: 10 March 1988

PROBLEM DESCRIPTION: The ImageWriter is unable to feed a single sheet of paper through without the paper slipping to one side.

CAUSE: Lightly pulling on the "slipped" side of the paper reveals that there is not much friction holding the paper positioned between the platen and the rollers.

CURE: Remove the the platen using the procedures in the Technical Procedures manual. Lightly rub the surface of the platen with fine steel wool to lightly roughen the surface and increase the friction between the platen, paper and rollers.

CAUTION: To prevent shorts from occurring on the logic board, be sure to thoroughly brush "all" steel wool particles off of the platen before reinstalling it.

If the above cure doesn't fix the problem, search on GTS and the product's name to obtain a general troubleshooting procedure.

Article Last Reviewed: 17 July 1992
Article Last Updated:

PROBLEM DESCRIPTION: A Macintosh 1/2 XL (originally called Lisa 2/5) may suffer from noise problems on its receiving lines. This interferes with its ability to hear other network devices, so may think it is safe to broadcast even if another node is transmitting. This can result in collisions that clobber other node's transmissions. The problem only happens with units that have the old I/O PCBs (the ones with battery packs).

CAUSE: The old I/O PCB needs to be upgraded.

CURE: 1. Cut R38 (location 12E above the battery pack).
2. Cut the trace leading to pin 3 of RP4 (location 12F)

If the above cure doesn't fix the problem, refer to the Lisa Tech Procedures to obtain a troubleshooting procedure.

LaserWriter P/C: Vertical Line or Blank Line on Page

=====

This article last reviewed: 10 March 1988

PROBLEM DESCRIPTION: From the top to the bottom of the page, either a solid line or blank line of variable thickness is printed.

CAUSE: There are six possible causes for this symptom:

- 1 - Defective toner cartridge
- 2 - Defective scanner unit
- 3- Dirty or bent primary or transfer corona wires
- 4 - Dirty fuser assembly or wiper
- 5 - Defective I/O board
- 6 - Defective DC controller board

CURE: First, perform a service print test and see if the same symptom is exhibited. If it is, the I/O board can be removed from the list of possible causes. If not, replace the I/O board and re-test.

If after the I/O board has been replaced or removed from consideration, replace each item, 2 through 6, rechecking for the problem after each replacement until the unit is printing properly.

If the above cure doesn't fix the problem, refer to the LaserWriter Tech Procedures to obtain a troubleshooting procedure.

Macintosh Continuously Reboots Itself

Revised: 1/17/92
Security: Everyone

Macintosh Continuously Reboots Itself

=====

Article Created: 22 April 1986
Article Last Reviewed: 17 July 1992
Article Last Updated:

PROBLEM DESCRIPTION: After being powered on the Macintosh continuously reboots of its own initiative. During this process, it beeps about twice a second.

CAUSE: The power supply may be defective.

IMPORTANT: To avoid damage to Macintosh modules follow the instructions exactly as given in the "CURE:" below.

CURE: 1. Replace the power supply.
2. Turn on the Macintosh and make all Level I adjustments.
3. Run MacTest. If the problem remains, replace the Main Logic PCB.
4. If the problem remains after step 3, replace the drive.

If the above cure doesn't fix the problem, search on GTS and the product's name to obtain a general troubleshooting procedure.

Macintosh: 512K With 800K Disk Drive

=====

Article Created: 22 April 1986
Article Last Reviewed: 17 July 1992
Article Last Updated: 17 July 1992

BACKGROUND: A 512K Macintosh requires a special revision of ROM to work with an 800K disk drive. Service stock PCBs commonly used as replacements when repairing Macintoshes do not have the 800K upgraded ROM installed.

IMPORTANT: When swapping the main logic PCB on a 512K Macintosh, perform the following:

1. CHECK FOR 800K ROM UPGRADE ON "BAD" PCB
Check the ROM installed on the malfunctioning PCB. If the ROM part numbers are 34X-0341 and 34X-0342, then they are 800K upgrade ROM and you should proceed to step 2 of this procedure. If not, then the bad PCB doesn't have 800K ROM so you don't need to worry about transferring the upgrade from the bad PCB to the new PCB.

2. SWAP 800K ROM FROM "BAD" PCB TO "NEW" PCB
If the malfunctioning PCB has the 800K ROM installed, swap them into the new PCB before installing it into the customer's Macintosh.

NOTE: If the ROM were swapped from the "BAD" PCB to the "NEW" PCB, remember to install the original ROM from the new service stock PCB into the bad PCB before returning it to Apple.

ImageWriter II Problem/Cure: Character Smudging

=====

This article last reviewed: 28 March 1988

PROBLEM DESCRIPTION: When using an ImageWriter II in conjunction with the Macintosh, characters sometimes appear "smudged" or "blurry".

CAUSE: This can often be a result of using other than the current version of ImageWriter II driver software.

CURE: First, to determine if the driver is the cause of the smudging, check the version of driver being used. The easiest way is to print a document and see what version number is displayed in the Print Dialog box. The version should be 2.1 or later. If it is not, the driver should be replaced.

To install the new driver, use the LaserWriter Install program contained on the LaserWriter Install diskette. (This diskette was sent to all dealers in the October 1 AppleGram mailing. The diskette is also included in all AppleTalk Option Kits for the ImageWriter, LaserWriter Plus Upgrade Kits, and LaserWriters.) Run the Install program and select "ImageWriter" as the print driver.

DON'T use the old method of dragging the current ImageWriter icon into the trash can and the new ImageWriter II icon into the system folder. This may result in a malfunction of the ImageWriter II.

If this cure does not resolve the problem, go to the Technical Procedures to obtain a general troubleshooting procedure.

Imagewriter: Controlling with BASIC (12/96)

Article Created: 24 April 1986
Article Reviewed/Updated: 16 December 1996

TOPIC -----

This article describes changing the Imagewriter's printing style from within a BASIC program.

DISCUSSION -----

A BASIC program can be used to change the Imagewriter's printing style. The Imagewriter User's Manual contains a listing of the different printer codes and their meaning.

The following sample program changes the type size to 17 characters per inch:

```
10 D$ = CHR$(4) : REM DOS and ProDOS commands access the printer.
15 REM CHR$(4) makes DOS or ProDOS look for a command.
20 PRINT D$;"PR#1" : REM Turn the printer interface card on.
30 PRINT CHR$(27); CHR$(113);
35 REM CHR$(27); and CHR$(113); change type to condensed size (17 CPI).
40 PRINT "THIS IS A TEST" : REM Print something to test the new style.
50 PRINT D$;"PR#0"
55 REM Turn off the printer interface card and turn on the screen output.
56 REM For 80 column screen output, replace the number 0 with the number 3.
60 END
```

Line 30 is the key to obtaining the smaller type size. The Imagewriter recognizes these two characters (27 and 113) as the command to change to condensed print. You will find these codes in the text of the Imagewriter User's Manual and on the foldout card in the back of the manual.

Use the foldout card to find the code for a feature you wish to use and enter the corresponding decimal codes in a print statement. For example, to obtain boldface printing, replace line 30 with the statement 30 PRINT CHR\$(27); CHR\$(33);

Some features have a series of n's in the decimal code column on the foldout card. Replace these n's with a number that has as many numerals as there are n's in the code, and PRINT the code with the number. For example, the foldout card shows that to set the left margin, send the characters Escape, L, and nnn or send the decimal codes 27, 76, and nnn. This means that the value of the left margin must be sent as a three digit number. If the margin value has only two digits, put an extra zero on the left. For example, to set the left margin to 15, replace line 30 with the statement 30 PRINT CHR\$(27); CHR\$(76); "015";

The Apple ImageWriter and Dot Matrix Printer have special modes which allow them to generate custom-design characters. To get the most definition for each character it is useful to be able to control all eight bits of the data being sent to the printer. The following program example illustrates the use of a routine which allows for all eight data bits to be significant. It demonstrates an example in the ImageWriter User's Manual Part 1: Reference on pages 69 and 70.

```
10 D$ = CHR$(4)
20 FOR I = 768 TO 773: READ J: POKE I,J: NEXT I
30 PRINT D$;"PR#1"
40 FOR I = 1 TO 14: READ J: POKE 769,J: CALL 768: NEXT I
50 PRINT CHR$(27)"*&&&" CHR$(27)"$"
60 PRINT D$; "PR#0"
70 DATA 169,4,76,237,253,96
80 DATA 27,45,27,73,166,71,0,72,72,126,72,72,0,4
```

* Line 20 reads the data from line 70 and POKE's a machine language routine into the computer.

* Line 30 activates the printer.

* Line 40 reads the data from line 80 which is a string of data defining a custom character, the plus/minus character as shown in the ImageWriter manual. It is defined using eight bit data where all eight bits are required.

* Line 50 uses the custom character.

* Line 60 returns the output to the screen.

Machine language programs: Determining the length of code

Revised: 4/24/86
Security: Everyone

Machine language programs: Determining the length of code

=====

In the case of a short machine language program, you just count the bytes to determine the length of code. This method is not practical for longer programs, though; for such programs, hexadecimal arithmetic is more useful. If you're familiar with hex digits (A = 10, B = 11, C = 12, D = 13, E = 14, F = 15), you can subtract hex locations, just like decimal numbers.

To discover the length of a longer machine language program, simply add 1 to the last location used by the machine language program, and then subtract from that the first location used by the program. For example, an ending address of \$0357 and a starting address of \$0300 would yield the calculation (\$0357 + \$0001) - \$0300, or a length of \$58:

last + 1	0	3	5	8
first	-	0	3	0
length		0	0	5

Likewise, the length of a program with an ending address of \$03AC and a starting address of \$031B is \$92:

last + 1	0	3	A	D
first	-	0	3	1
length		0	0	9

In each case above, the answer is the length of the machine language program, and you may use it in a BSAVE command:

BSAVE PROGRAM, A\$0300, L\$58

You'll find more extensive explanations of hexadecimal arithmetic in most introductory machine language books. Check with a local book store or Apple dealer to help you locate one.

Apple Access II: 1.1 Update

=====

The new version of Access II (1.1) solves many of the bugs that were associated with Access 1.0. Here are the main changes:

- Text file send delay (The 1.0 version would only accept 99 as a value when the maximum input should have been 9999)
- XMODEM file transfer (Access 1.0 would 'lock-up' during XMODEM transfers and the file would be lost)
- Formatting routines (The formatting routines now operate)

The Access II 1.1 upgrade may be obtained by the user through the Apple media exchange program.

Macintosh Plus: Problems with Chooser Versions Earlier Than 3.1

=====

Article Created: 24 April 1986
Article Last Reviewed: 27 May 1992
Article Last Updated: 10 November 1987

The following information applies only to versions of the Chooser earlier than 3.1.

A Macintosh Plus or Macintosh 512K Enhanced often have difficulty initializing the serial port for AppleTalk other than at power up.

This becomes obvious when you've physically connected AppleTalk to your system, clicked on Connect AppleTalk in the Control Panel (Apple menu) and your LaserWriter or ImageWriter (with an AppleTalk card) connected to the network still doesn't appear in the Chooser.

Try closing then reopening the Chooser; if your printer still doesn't display in the Chooser, you'll need to power down and back on. After power back on, you'll then be able to Choose any printer connected to your AppleTalk network.

If you still are unable to select your printers, perform the above steps again. Additionally, make sure you've installed the necessary drivers with the Installer: check the System Folder. There you should find drivers for each of your printers. For example, if wish to print to a LaserWriter, then in the System Folder you should find an icon named LaserWriter and one named LaserPrep.

Apple Tape Backup 40SC: Restore "Volume" Backup To Original Disk

=====

This article last reviewed: 7 January 1988

You can use either the "Backup Files" or "Backup Volume" option on the Tape Backup 40SC, but "Volume" backups should be restored only to the SAME hard disk. "File" backups may be restored to any hard disk that have enough room to store the files from the original hard disk.

Distributing backup material by tape is also possible -- as long as the backup of the original material was done using the "Backup Files" option. If you use the "Backup Volume" option, the hard drive you are restoring to must have exactly the same number of blocks as the original hard drive.

Macintosh Plus: Connecting it to an AppleLine

=====

This article last reviewed: 9 October 1987

There are two ways to connect a Macintosh Plus to AppleLine:

- 1) use the 590-0169A Cable and the Mini Din 8 to DB-9 Adapter.
- 2) use the A2C0311 590-0331-B Tan, or the A2C0312 590-0555-A Platinum cable. These cables have a DIN 8 at one end and a 25 pin on the other, AppleLine end.

Note: The second method has been shown to be generally more reliable than the first.

AppleWorks: Using it with the IIfx and the Epson DX-20 printer

=====

This article describes how to run AppleWorks on a IIfx with an Epson DX-20 printer.

Configuration:

- Apple IIfx
- Super Serial Card
- CompuCable, P/N MTB0201
- Epson DX-20 Letter Quality Printer
- AppleWorks, version 1.3

Super Serial Card switch settings:

SW 1-1: OFF	SW 2-1: ON
SW 1-2: ON	SW 2-2: OFF
SW 1-3: ON	SW 2-3: OFF
SW 1-4: ON	SW 2-4: OFF
SW 1-5: ON	SW 2-5: ON
SW 1-6: ON	SW 2-6: OFF
SW 1-7: ON	SW 2-7: OFF

DX-20 switch settings:

SW 1-1: OFF	SW 2: all OFF
SW 1-2: OFF	
SW 1-3: ON	
SW 1-4: OFF	
SW 1-5: OFF	
SW 1-6: ON	
SW 1-7: OFF	
SW 1-8: OFF	

AppleWorks configuration:

Needs line feed after each return:	NO
Accepts top-of-page commands:	NO

Stop at end of each page: YES or NO (NO is preferable)

Platen width: 13.0

Printer codes:

Characters per inch: no codes

Lines per inch: no codes

Boldface, subscript and superscript:

Boldface begin: ESC-W

Boldface end: ESC-&

Subscript begin: ESC-U

Subscript end: ESC-D

Superscript begin: ESC-D

Superscript end: ESC-U

Underlining (printer has start/stop underlining commands):

Underlining begin: ESC-E

Underlining end: ESC-R

MacTerminal 2.0: Terse mode

Revised: 9/1/87
Security: Everyone

MacTerminal 2.0: Terse mode

=====

Numbered responses from the Personal Modem are more efficiently interpreted by MacTerminal 2.0 than are string responses, so MacTerminal 2.0 puts the Personal Modem into this "terse" mode by issuing the command `ATV0`. In terse mode, the Personal Modem returns numbers instead of strings in response to commands, such as returning a zero in place of the response string "OK".

You can take the Personal Modem out of terse mode by typing `ATV1`. The Personal Modem responds to this command with the string "OK".

If you wish to reset all defaults, including the display of strings rather than number codes, use `ATZ --` or, of course, turn the modem off and then on.

Super Serial Card: Accessing it through Machine Language

=====

Although Apple's Super Serial Card can be used from Applesoft Basic, it is often desirable to use machine language to increase the speed with which characters are sent and received. The assembler program below illustrates a method of communicating with another Apple computer through the Super Serial Card. You may use this routine as a starting point for your own program.

On page 291 of the Apple IIe Reference manual and on pages 261 to 265 of the Apple IIc Reference Manual there are lists of the registers and entry points used by routines resident in the Super Serial Card. The equates in the program below use these locations, as well as input/output hooks found in the Apple II family of computers.

The initialization routine (INIT) stores the address of the Super Serial Card's initialization routine in CSW (the Apple II monitor character output hook). This activates the card for output by jumping to COUT. Following this, DOS or ProDOS hooks are reinstalled.

The OUTPUT routine checks the 6551 status port bit 4. If this is equal to zero, the previous character has not yet been sent, so we must check the status byte again until that register is clear. When the value in bit 4 becomes one, the 6551 is ready to send another character. To accomplish this, simply store the data in the transmit register (TDREG) of the chip.

Bit 3 of the status port is checked by the INPUT routine. If this bit is zero, the program either loops continuously or returns to the calling program, depending on the state of the return flag found in location \$FF. If bit 3 is one, a character is waiting at the input port, and the character is then read from the read register (RDREG) of the 6551.

The DEMO portion of this program calls the INIT routine, and sends each letter of the alphabet to the connected device. After each character is sent, the program waits to see if a response has been received from the external device. If a character is waiting, the program ends.

Mac Plus, SE, and II: Memory Configuration and Speed (5/95)

Article Created: 22 January 1988
Article Reviewed/Updated: 1 May 1995

TOPIC -----

With the advent of larger SIMMs (single inline memory modules), there are several ways to configure a Macintosh Plus, Macintosh SE, or Macintosh II.

DISCUSSION -----

Macintosh Plus and SE
=====

The Macintosh Plus and Macintosh SE can be configured in five ways:

- 512 KB
- 1 MB
- 2 MB
- 2.5 MB
- 4 MB

Memory expansion must follow strict guidelines that involve modification of the Macintosh logic board and correct placement of the SIMMs.

On a Macintosh Plus or Macintosh SE logic board are four SIMM sockets, labeled SIMM1 through SIMM 4. These sockets are paired, 2 banks of 2 sockets each.

For the Mac Plus:

	68000
	SIMM 1
Bank A	
	SIMM 2

For the Mac SE:

	68000
	Bank A
SIMM 1	SIMM 2
	Bank B

 . Logic Board (front)

 Logic Board (front)

- Bank A comprises SIMM 1 and SIMM 2; Bank A, the 2 slots towards the rear of the logic board.
- Bank B comprises SIMM 3 and SIMM 4; Bank B, the 2 slots towards the front of the logic board.

Both sockets in each pair must configured identically. For example, both SIMM sockets 3 and 4 must contain either 256K or 1MB SIMMs, or be empty.

The RAM density of the chips in Bank A must be greater than or equal to the RAM density of the chips in Bank B. For example, if Bank A contains 256K SIMMs, Bank B may be empty or contain 256K SIMMs, but not 1MB SIMMs.

Some configurations require changes to the logic board. There are two resistors that tell the Macintosh important information about what kind of SIMMs are installed.

- If you have only one row of SIMMs installed (say, Bank A has 1MB SIMMs installed and Bank B is empty), then the resistor marked "ONE ROW" must be present; otherwise it should be cut or removed. (The Macintosh Plus and Macintosh SE are not shipped with this resistor installed.)
- If your computer has 256K SIMMS in Bank A, then the resistor marked "256K BIT" must be installed. If either or both Banks have 1MB SIMMs, then the resistor must be cut or removed. (The Macintosh Plus and Macintosh SE come with the resistor installed.)

Here's a chart that shows all the currently possible SIMM configurations and resulting memory total for the Macintosh Plus and Macintosh SE:

.	Bank A	256K	256K	1MB	1MB	1MB
.	Bank B	empty	256K	empty	256K	1MB
.	256K Resistor	present	present	absent	absent	absent
ONE ROW Resistor	present	absent	present	absent	absent	absent

	Total Memory	512K	1MB	2MB	2.5MB	4MB

Macintosh II
 =====

There are currently four SIMM sizes for the Macintosh II:

- 512 KB
- 1 MB

- 4 MB
- 16 MB

The Macintosh II requires special 4MB SIMMs. Be sure to specify your Macintosh model when ordering these SIMMs and ensure that the vendor is aware of the difference. The Macintosh II requires the SuperDrive (FDHD) Upgrade to use 4MB or 16MB SIMMs.

To take advantage of more than 8MB of physical RAM, the Macintosh II MUST have a PMMU installed, so that MODE32 can expand the system's memory map.

With the original ROMs, the Macintosh II will not start up if you install 4MB or 16MB SIMMs in bank A. You'll hear musical chimes at startup, indicating a hardware failure. Install 4MB SIMMs in bank B, and use 256K or 1MB SIMMs in bank A. This provides a maximum of 68MB of RAM installed.

With the FDHD ROMs installed, up to 16 MB SIMMs are supported in bank A increasing the maximum memory configuration to 128 MB.

Restrictions on placing SIMMs in the Macintosh II are similar to those for the Macintosh Plus and Macintosh SE: the SIMM sockets are divided into two banks, A and B, each containing four SIMM sockets. All SIMMs in either bank must be of the same type. No resistors need to be cut to differentiate between the possible configurations.

With original ROMs:

Bank A	256K	to a Maximum	1 MB
Bank B	empty		16 MB
-----	-----		-----
Total Memory	1 MB		68 MB

With FDHD ROMs:

Bank A	256K	to a Maximum	16 MB
Bank B	empty		16 MB
-----	-----		-----
Total Memory	1 MB		128 MB

SIMM Speed Ratings

=====

- Macintosh Plus: SIMMs must be rated 150ns or faster (the number on the SIMM must be 150 or smaller)
- Macintosh SE: SIMMs must be rated 150ns or faster (the number on the SIMM must be 150 or smaller)
- Macintosh II: SIMMs must be rated 120ns or faster (the number on the SIMM must be 120 or smaller)

3.5 Disk Drive: Ejection Problems

Revised: 4/9/91
Security: Everyone

3.5 Disk Drive: Ejection Problems

=====

This article last reviewed: 28 March 1988

Whenever a diskette from either a 800K Macintosh internal or external or a UniDisk 3.5 disk drive does not fully eject, the user must push the diskette back in and attempt to eject it electronically. For the Macintosh, this can be done by holding down the <SHIFT> and <COMMAND> (cloverleaf) keys and pressing '1' (for the internal drive) or '2' (for the external drive). The EJECT command from the FILE menu can also be used. For the UniDisk 3.5, the user can press the eject button on the front of the UniDisk. For either disk drive, the user should attempt this two or three times. As a last resort, a large paper clip can be inserted into the pin hole located to the right of the slot where the disk is inserted.

NOTE: Misalignment of the drive mechanism relative to the bezel, might cause extra drag friction on the floppy that is being ejected and thus cause the eject cycle to be interrupted. The June 1986 Service Mailing will instruct dealers on how to perform this alignment procedure.

IMPORTANT: Once the diskette becomes "frozen" and does not fully eject, the user must NOT force the diskette by pulling it out from the drive. Doing so can cause possible damage to the disk drive mechanism. If the user has tried to forcibly remove the diskette from the disk drive, refer to "Removing Diskettes Which Will Not Eject" below.

In addition to the precautions discussed above, the user should be aware of other factors which can affect the insertion and ejection of a diskette.

- A diskette should be inserted by pressing the diskette gently into the drive. Avoid grasping and pushing the diskette, as this may cause the diskette to go in only part way and stop. If this happens the user should attempt to eject the diskette as described above.

- Diskettes which contain three or more labels may not slide easily into and out of the diskette slot in the case. Should a third label be required, either the other labels should be removed first or the diskette should be discarded.

Technicians should also exercise care when removing or installing a Macintosh Internal disk drive mechanism. If the diskette opening in the disk drive mechanism is not properly centered, binding or friction may cause ejection problems. Refer to the Macintosh Technical Procedures for the proper installation procedures.

REMOVING DISKETTES WHICH WILL NOT EJECT

If a diskette becomes "jammed" in a customer's disk drive, the following procedure should be used to remove it prior to returning the disk drive.

1. Remove the disk drive. Refer to the Technical Procedures to do this.
2. If the disk drive is a Macintosh Internal drive, remove the RFI shield from the mechanism.
3. Place the disk drive mechanism on a flat surface, with the Printed Circuit Board facing down and the diskette opening facing you.
4. If the diskette is not already fully inserted into the disk drive, push it in until it is properly seated.
5. Press the eject lever at the right side of the disk drive.
6. Turn the disk drive so that the left side is facing you.
7. Located the small arm with a cylindrical cog at its end. This arm is located near the left-to-right center of the drive mechanism. This cog will be caught in the half-moon depression of the diskette case.
8. Insert a small screwdriver between the arm mentioned in step 7 and the diskette case. Gently move the arm away from the diskette until the diskette pops forward slightly. Remove the diskette from the disk drive.
9. Return the defective disk drive to Apple and follow the instructions in Technical Procedures to replace the disk drive with a new unit.

Ethernet: Cable and Network Specifications

=====

This article last reviewed: 7 January 1988

When ordering and installing Ethernet cable, be sure the cable and network meet the following defined physical specifications:

	10BASE5 (Ethernet)	10BASE2 (Cheapernet)
Cable	0.4 in diameter 50 ohm Double Shielded	0.2 diameter 50 ohm (RGA58A/U) Single Shielded
Segment Length	500 m	185 m
Network Span	2500 m	925 m
Nodes per Segment	100	30
Node Spacing	2.5 m	0.5 m min
Capacitance per Node	4 pf max	8 pf max

Apple EtherTalk Card: Supports TCP/IP With NCSA Telnet

Revised: 10/4/89
Security: Everyone

Apple EtherTalk Card: Supports TCP/IP With NCSA Telnet

=====

This article last reviewed: 7 January 1988

The National Center for Supercomputer Applications offers NCSA Telnet Version 2.1e, a communications program that supports TCP/IP with the Apple EtherTalk card.

Telnet Version 2.1e includes file transfer and Tektronix terminal emulation. Because network access is via NuBus, and is not bottlenecked by the AppleTalk port, performance is better than with FastPath.

Although Telnet Version 2.1e is in public domain, there is a charge for handling and diskettes. (Specify the Macintosh version.)

For more information, search under: National Center for Supercomputer Applications.

I. Technical Specifications

A. Picture Tube:

- 12-inch diagonal (11.5-inch viewable)
- 0.37 mm tri-dot-pitch high contrast (black matrix)

B. Input Signal:

- Analog
- Red, green, blue video signals composited with negative going synchronous 1.0+/- 0.5 volts peak to peak, internally terminated with 75 ohm resistors. Composite synchronous negative going 4.0 +/- 1.0 volts peak to peak, internally terminated with 2000 ohm resistor.

C. Scanning Frequencies:

- | | System: NTSC/60 | NTSC/50-PAL/50 |
|----------------|-----------------|----------------|
| 1. Horizontal: | 15.734 kHz | 15.659 kHz |
| 2. Vertical: | 60 Hz | 50Hz |

D. Video Bandwidth:

- Flat within 1.5 DB to 6.5 MHz. Less than 3 DB down at 8 MHz.

E. Resolution:

- 640 horizontal by 200 vertical pixels when used with the Apple IIGS.

F. Active video display area:

-- Adjusted at the factory to produce an active video area of
200 mm horizontal by 150 mm vertical.

-- Remainder of display area is used for border display area.

G. User Controls:

1. Power switch (right side)
2. Contrast (right side)
3. Brightness, with detent reference (right side)
4. Vertical size (back panel)
5. Vertical hold (back panel)
6. Horizontal hold (back panel)

H. Physical:

|------------|---------|--------------|
| 1. Height: | 281 | 11 |
| 2. Width: | 344 | 13.5 |
| 3. Depth: | 405 | 16 |
| 4. Weight: | 12.5 kg | 27.56 pounds |

I. Electrical

1. Power Requirements:
 - Less than 65 watts under normal viewing conditions.
 - 90 watts maximum.

2. Input Voltage:

Model	Operating Range	Power Frequency
a. 120 v	108-132	50-60 Hz
b. 220 v	198-242	50-60 Hz
c. 240 v	216-264	50-60 Hz

3. Fuse Protection:

-- The monitor contains internal power line fuse protection.
This fuse should be replaced with the same type by a
qualified service technician.

4. Interface:

-- 15-pin D-style connector
-- Apple IIGS cable

J. Environmental (Operating):

- | | Celsius | Fahrenheit |
|---------------------------|---------|------------|
| 1. Temperature (ambient): | 0-50 | 32-122 |

2. Humidity: 90% maximum
3. Altitude: 10,000 feet maximum

A. Storage:

1. Formatted data capacity: 20 megabytes
2. Data surfaces: 4
3. Heads per surface: 1
4. Block size: 512 bytes
5. Total disk blocks: 39,360
6. Sectors per track: 32

B. Drive:

- Winchester technology
1. Average access time: 65 to 85 milliseconds
 2. Data transfer rate: up to 1.25 megabytes per second
 3. Rotation speed: 2,744 RPM
 4. Startup: 9 seconds
 5. Spindown: 20 seconds

C. Interfaces

-- Two 50-pin connectors

-- One expansion port, a "pass-thru" SCSI port, allows for connection of second HD20 or backup device

D. Electrical

-- Automatically adapting to supply

1. Line voltage: 85 to 270 volts AC, RMS

2. Frequency: 47 to 64 Hz

3. Power consumption: 60 watts

E. Environmental

1. Temperature:

Degrees		
	Celsius	Fahrenheit
a. Operating:	10 to 40	50 to 104
b. Storing:	-40 to 50	-40 to 122

2. Relative humidity: 20 to 80 percent (noncondensing)

3. Altitude:

	feet	meters
a. Operating:	-1000 to 10,000	-305 to 3,050
b. Nonoperating (shipping):	-1000 to 40,000	

F. Physical

	mm	inches
1. Height:	78	3.1
2. Width:	246	9.7
3. Depth:	266	10.5
4. Maximum weight:	3.63kg or 8 pounds	

II. System Configuration

A. Cable: Apple SCSI System Cable

B. Connector:

1. SCSI port of Macintosh Plus, Macintosh SE, Macintosh II

2. SCSI connector of Apple II SCSI Card for:

- a. Apple IIGS
- b. Apple IIe
- c. Apple II Plus

LaserWriter II: Connecting an MS-DOS Computer (5/96)

Revised: 6/5/96
Security: Everyone

LaserWriter II: Connecting an MS-DOS Computer (5/96)

=====

Article Created: 17 June 1988
Article Last Reviewed/Updated: 05 June 1996

When you configure the DIP switches (or push-button switch) of a LaserWriter II series printer for the appropriate communication channels, default parameters are also set for baud rate, parity, and data/stop bits.

For example:

On the LaserWriter IINT, setting switch 1 up and switch 2 down configures both serial ports to the PostScript batch mode at 9600 baud, 8 data bits, 1 stop bit, ignore parity, and XON/XOFF.

The MS-DOS computer must be configured to match the LaserWriter's communication parameters. Type these two MS-DOS commands to set baud to 9600, parity none, 8 data bits, 1 stop bit:

```
MODE COM1:96,N,8,1,P
MODE LPT1:=COM1
```

These commands, vary depending on the current settings of the LaserWriter with which the computer will be communicating. They must be updated each time the LaserWriter parameters are changed.

Handshaking must also match; MS-DOS computers typically use DSR/DTR -- the LaserWriter defaults to XON/XOFF. Some MS-DOS applications allow you to change the handshake protocol; if not, you will have to configure the printer to conform to the computer's handshake.

On the LaserWriter IINTX, handshaking is controlled by switches 5 and 6; setting switch 5 up and switch 6 down configures the printer to use DSR/DTR. It is possible to override these settings through a PostScript program.

On the LaserWriter IINT, handshaking must be configured by sending a PostScript program for changing parameters with options encoded for the

appropriate values for the compatible handshake method. To set the DB-25 port for communication at 9600 baud and with DTR handshaking on the LaserWriter, send this PostScript program:

```
serverdict begin 0 exitserver
statusdict begin
25 9600 4 setsccbatch
end
```

On the Laserwriter II_f and II_g, these settings are adjusted with a push-button switch, not with DIP switches. The switch setting configurations are documented in the following table.

Begin_Table

Switch setting	Mode	Baud	Data	Stop	Parity	Handshaking
0	Postscript	9600	8	1	N	XON
1	HP PCL4	9600	8	1	N	DTR
2	Postscript	19200	8	1	N	XON
3	<inactive>					
4	Postscript	1200	7	1	N	XON
5	Postscript	9600	8	1	N	XON
6	Postscript	19200	8	1	N	XON
7	Postscript	1200	8	1	N	DTR
8	HP PCL4	1200	8	1	N	XON
9	Postscript*	9600	8	1	N	XON

*switch setting 9 sets printer to postscript binary

End_table

More information on changing parameters on the LaserWriters can be found in current Apple LaserWriter Reference manuals, and current PostScript Language Reference Manuals. See the manuals that came with your MS-DOS computer for more information on communication configuration.

 - d. Stack pointer
 - e. Program counter
7. 8-bit registers:
 - a. Data bank
 - b. Program bank
 - c. Status
8. Addressable memory (as used in the Apple IIGS):
 - a. RAM: Up to 8 megabytes
 - b. ROM: Up to 1 megabyte

B. Memory

1. RAM: 256 kilobytes
 - Expandable to 8 megabytes
2. ROM: 128 kilobytes
 - Expandable to 1 megabyte
 - a. Control Panel
 - b. QuickDraw II graphics routines
 - c. Applesoft BASIC
 - d. Desk Accessory Manager
 - e. Memory Manager
 - f. Free-form sound playback capabilities
 - g. Apple IIe and IIc soft switches and supporting code
 - h. AppleTalk protocols
 - i. Apple DeskTop Bus firmware
 - j. SANE (trademark) numerics
 - k. Event Manager
 - l. Tool Locator
 - m. Video firmware
 - n. Drivers for built-in devices:
 - Mouse and ports for serial interface and disk drive
 - o. Extensions to system monitor for 65C816 support
 - p. Diagnostic routines

C. Display modes

1. Graphics
 - a. Super-high-resolution
 1. 320 dots horizontally by 200 dots vertically
 - Colors per line: Up to 16
 - Colors per screen: 256 from 4096
 2. 640 dots horizontally by 200 dots vertically
 - Colors per line: 4 or more
 - Colors per screen: 128 from 4096
 - b. Double-high-resolution
 - 560 dots horizontally by 192 dots vertically
 - Monochrome
 - c. Double-low-resolution
 - 80 dots horizontally by 48 dots vertically
 - Colors: 16
 - d. High-resolution
 - 280 dots horizontally by 192 dots vertically
 - Colors: 6
 - e. Low-resolution
 - 40 dots horizontally by 48 dots vertically
 - Colors: 16
2. Text
 - a. 40-column text mode
 - 40 columns by 24 lines
 - b. 80-column text mode
 - 80 columns by 24 lines

D. Character sets

1. Letters
 - a. Uppercase: 32
 - b. Lowercase: 32
2. Characters:
 - a. Special: 32
 - b. MouseText: 32
 - c. Unique: 12
 - For each international character set: U.S., U.K., French, Danish, Spanish, Italian, German, and Swedish

E. Keyboard

- Standard typewriter-style
- 1. Keys:
 - a. Main board: 80
 - b. Numeric keypad: 14
- 2. Apple DeskTop Bus (ADB) connectors: 2
 - a. For attaching keyboard to computer
 - b. For daisy-chaining a maximum of 16 ADB input devices
- 3. Layouts: 11
 - Selected through Control Panel
 - a. QWERTY (Sholes)
 - b. Dvorak
 - c. International sets: 9
 - U.S., French Canadian, U.K., French, Danish, Spanish, Italian, German, and Swedish

F. Sound capability

1. Ensoniq 32-oscillator digital synthesizer chip
 - Dedicated 64K RAM
2. Simultaneous voices: Up to 15
3. Output:
 - a. Internal speaker
 - b. Audio output jack:
 - Inside diameter 3.60mm
 - Accepts a 3.5mm stereo plug
 - c. Signal-to-noise ratio: 48bd
 - d. Volume adjusted from Control Panel

G. Interfaces

1. Expansion slots

..TIL01937-Apple_IIGS-Specifications_Discontinued.pdf

- a. Multipurpose RAM and ROM expansion slot
- b. General purpose input/output slots: 7
 - For peripheral control cards
 - Each slot fully buffered
 - Interrupt and DMA priority
- 2. Serial ports: 2
 - 8-pin mini-circular connectors
 - AppleTalk
 - Utilize SCC communication chip
- 3. Disk drive port:
 - 19-pin D-style connector
 - Supports daisy-chaining
- 4. Video output
 - a. Analog RGB via 15-pin D-style connector
 - b. Composite color via RCA phono connector
- 5. Apple DeskTop Bus ports: 3
 - 4-pin mini-circular connector
 - a. On back of IIGS: 1
 - b. On keyboard: 2
- 6. Game I/O: 9-pin D-style connector
 - For joysticks, graphics tablet, etc.
- 7. Audio
 - a. RCA mini jack
 - Programmable volume control
 - b. Input/output connector on main logic board

H. Operating systems

- 1. ProDOS (registered trademark):
 - a. ProDOS 8
 - b. ProDOS 16
- 2. Pascal
- 3. DOS 3.3
- 4. CP/M
 - With appropriate co-processor card

I. Other Features

- Real time clock
 - Set through Control Panel
- Battery backup for Control Panel settings

J. Electrical

1. Line voltage: 107 to 132 volts AC; 50 to 60 Hertz

2. Power consumption:

-- Typical: 11 watts

-- Maximum: 60 watts

3. Supply:

	Voltage in volts	Voltage Tolerance	Maximum current in milliamps (ma)
a. + 5		3%	2500 ma
b. +12		6%	1500 ma
c. - 5		10%	250 ma
d. -12		10%	250 ma

4. Safety and EMI qualifications

a. FCC Part 15, Class B Computing Devices

b. CSA 22.2, No, 154-1979

c. UL 114-Office Appliances and Business Equipment

K. Environmental

		Degrees Celsius	Fahrenheit
1. Ambient operating temperature:	0 to 45		32 to 113
2. Maximum temperature			
	on power supply case:	55	130

3. Relative humidity: 5% to 85%

L. Physical

	mm	inches
1. Width:	284	11.2
2. Depth:	348	13.7
3. Height:	117	4.6
4. Weight:	3.96kg or 8.72 pounds

13	DB7' Data Line 7	33
14	GND Ground	1,2,3
15	C/D' Carrier Detect	48
16	GND Ground	4,5,6
17	ATN' Attention	41
18	GND Ground	7,8,9
18	DIFFSENS-GND	11
19	SEL' Select	47

20	DBP'	Parity	34
21	DB1'	Data Line 1	27
22	DB2'	Data Line 2	28
23	DB4'	Data Line 4	30
24	GND	Ground	23,24,25
25	TERMPWR		38

Important SCSI Card Information

=====

The prime (') next to the signal name indicates the signal voltage levels are negative, "low true". The SCSI port uses -5V logic levels.

Because the SCSI port is a DB-25 connector, it looks like a RS-232 port but is NOT a RS-232 port. DO NOT plug any RS-232 device into the SCSI port. Doing so can damage the 5380 chip on the card.

Apple IIGS: A descriptive list of tools in the IIGS Toolbox

Revised: 10/6/86
Security: Everyone

Apple IIGS: A descriptive list of tools in the IIGS Toolbox

=====

Among other features, the Apple IIGS' built-in Toolbox distinguishes the Apple IIGS from earlier Apple II's in that IIGS applications can call the Toolbox routines like Macintosh applications can call the Macintosh Toolbox. Supporting the desktop user interface, the IIGS Toolbox makes developing new applications easier.

1. Tool Locator

The Tool Locator provides the mechanism for dispatching tool calls. It maintains vectors to all of the managers and their associated routines and allows for the patching of these routines with RAM tools or substitutions.

2. Memory Manager

Controlling memory allocation, the memory manager attempts to parcel out sections of memory for an application's use in response to a request by that application. If the memory manager cannot grant that request because of lack of memory, then it is up to the application to deal with an "Out Of Memory" error condition.

3. QuickDraw II

Many of the routines in QuickDraw II are the same as those in the Macintosh. However, QuickDraw II does have the added capability of drawing in color (in both 320 and 640 resolution).

4. SANE Numerics

SANE stands for Standard Apple Numeric Environment. An extended-precision floating point routine package, it conforms to IEEE standard (754) arithmetic.

5. The Desk Accessory Manager

The Desk Accessory Manager keeps track of active Desk accessories on

the desktop. On the Apple IIGS, there are two types of Desk Accessories: classic desk accessories that can run either in the Apple IIGS desktop environment or with old-style applications (like AppleWorks) and new desk accessories that run only in the Apple IIGS desktop environment.

6. Event Manager

This manager is responsible for keeping track of events that occur in the computer system while the current application is doing something else. The application can, when it is done with its current task, ask the event manager what happened while it was busy, and the manager will return a record describing the events that occurred.

7. Menu Manager

This manager is responsible for the maintenance and selection of menus and their associated items. It handles both mouse and keyboard selection.

8. Window Manager

This manager is responsible for keeping track of which areas are covered by which windows including overlapping windows. Whenever a mouse down event is detected, the application calls this manager to find out in which window the event took place.

9. Control Manager

Controls are little "hot spots" on the screen; clicking in controls gives the application commands: yes/no buttons, check boxes, and scroll bars. The control manager is responsible for the placement of these controls on the screen and for alerting the application when the user clicks the mouse in one of them.

10. Line Editor

The Line Editor provides a standard text input interface. Text can be entered, deleted, cut, and pasted within limits.

11. Dialog Manager

This manager is responsible for placing alert messages and text-filled boxes on the screen.

12. Scrap Manager

This manager is responsible for handling the transmission of data from one application to another, often appearing as the clipboard or the scrapbook.

13. Print Manager

The print manager provides for a standard interface for applications among the many printers available for the Apple IIGS.

14. Integer Math Tools

These are a series of fast, extended-precision routines for arithmetic on integer numbers only.

15. Sound Manager

The Sound Manager, a set of routines that controls the Digital Oscillator Chip (DOC) and the Note Synthesizer, oversees the transmission of data to the sound RAM and activates and deactivates all of the 15 voices the Apple IIGS can produce.

16. The Scheduler

Much of the system code in the Apple IIGS is not re-entrant. This means that an interrupt routine cannot call the section of code that was running when the interrupt occurred. The Scheduler makes it possible to delay the execution of tasks that require non-re-entrant system code whenever that code is already in use.

17. Miscellaneous Tools

These tools allow modifying of battery RAM (Control Panel settings) and the clock chip, preparing interrupts and installing interrupt handling routines, as well as mouse control, data compaction, and other small but necessary routines.

LaserWriter IIntx: Speed Up Printing with Font Caching

Revised: 9/22/89
Security: Everyone

LaserWriter IIntx: Speed Up Printing with Font Caching

=====

This article last reviewed: 15 January 1988

PostScript printer fonts -- outline fonts -- are defined as mathematical constructs that form the outline of the character. Each font (for example: Helvetica 12 bold, Times 18) must be converted into bitmaps before it can be printed on the LaserWriter. The bitmapped characters are stored (cached) in RAM; they will remain in RAM until the memory space is required by other bitmapped fonts, or by other system tasks. Each time a font that is no longer in the memory is required for a document, it must be reconstructed.

You can decrease the need to rebuild font bitmaps on a LaserWriter IIntx by adding RAM and/or attaching SCSI hard disks. When additional fonts must be downloaded and cached, RAM is checked first for available caching space. If no RAM is available, and the existing cached fonts are not needed by the current job, they will be replaced. If all RAM-cached fonts are used in the present print job, the new font will be cached in the space on the hard disk allocated for font-caching. This eliminates the need to reconstruct the bitmaps of those fonts which would have been removed if no hard disk space were available, and if RAM caching had exceeded its limits.

LaserWriter II: Specifications (Discontinued 2/88)

=====

This article last reviewed: 27 April 1988

Here are the technical specifications for a LaserWriter II:

Printing Method

Electrophotography (single-component dry toner)

Printing Speed

Cassette Feed: 8 prints/ minute (other than legal size)
7 prints/ minute (legal size)

Optical System

Laser: semiconductor laser
Scanning System: rotating 6-faced prism mirror

Paper

Cassette Feed 16 to 24 lbs. single sheet photocopy bond
Manual Feed 16 to 36 lbs. letterhead and colored stock
Standard Weight transparency material
Envelopes and labels

Cassettes/Capacity/Sizes

Auto 200 sheets: US Letter, Legal, A4, B5
Manual Single sheets: US Letter, Legal, A4, B5
Envelope 15 envelopes

Print delivery/Capacity

Face-down 100 sheets
Face-up 20 sheets

(NOTE: Always open the face-up tray when printing stock above 21 lbs., or when printing envelopes or transparencies.)

Duty Cycle (month) No limit

Minimum life expectancy: 300,000 pages

Service Interval: 100,000 pages

Pages per Toner: 4000 pages

Noise Level

Printing Under 60 dB(A)

Standby Under 50 dB(A)

Dimensions W 20.2" x D 18.7" x H 8.7"

Weight 46 lbs.

Power Consumption

Standby Average 170W

Operating Maximum 900W (115V)

780W (220V)

880W (240V)

Line Voltage requirements Voltage (V) 10% Frequency (Hz)

US/Japan 100/115 50/60

Europe/Australia 220/240 50

LaserWriter IIsC: How It Handles Fonts

Revised: 1/21/88
Security: Everyone

LaserWriter IIsC: How It Handles Fonts

=====

This article last reviewed: 15 January 1988

Four times (4X) fonts are provided for the LaserWriter IIsC so the resolution image created in the off-screen bit-map by the LaserWriter IIsC driver will correspond to the resolution of the printer. Because these fonts are bit-mapped fonts, they can be printed directly from the Macintosh screen to the LaserWriter IIsC. Any intrinsic font (a font whose characteristics are entirely defined by a font resource) can be used by the LaserWriter IIsC without modification.

Because the full set of LaserWriter IIsC fonts requires 1.5 megabytes of storage, only the plain intrinsic fonts are included. Sources of additional fonts will be third party developers, shareware, etc. Or you can create your own fonts by using a third party program such as FONTastic by AltSys.

The five style selections (bold, italic, underline, outline, shadow) can easily be derived by QuickDraw. QuickDraw uses an algorithm to derive the desired style if the intrinsic font is not available. The information necessary for calculating a specific style is stored in the font family record, FOND.

The LaserWriter IIsC driver requests a scaling factor of 4:1 when intercepting the QuickDraw commands to the Font Manager. If you select a font for which there is not an associated four times (4X) font in the system file, the Font Manager uses an algorithm to find another font that can be scaled ("scaling" refers to the resizing, compression, or expansion of a character by QuickDraw.)

The LaserWriter IIsC does not support font substitution.

LaserWriter Font Utility: It Has Four Basic Functions

=====

Article Created: 2 March 1988
Article Last Reviewed: 5 November 1991
Article Last Updated: 18 October 1988

TOPIC -----

This article describes the functions of the LaserWriter Font Utility.

DISCUSSION -----

The LaserWriter Font Utility Application located on the LaserWriter II installation disk provides four basic functions:

- Initialization of disk devices attached to the LaserWriter IIntx. Initialization allots 20 percent of total disk space to font storage and 80 percent to font-caching.

NOTE: The following functions can be used with any AppleTalk LaserWriter.

- Display all available fonts -- built-in ROM fonts, downloaded RAM fonts, downloaded disk device fonts. You are given the option of deleting fonts which have been downloaded to a disk device.
- Download fonts - When you download a font (AND you have a hard disk attached,) you can choose to download it either to the disk or to RAM. Downloading it to the disk stores it there permanently (or until you remove it.) Those fonts downloaded to RAM remain there until the LaserWriter is powered-down.
- Print Catalog of available fonts (same as display fonts) and their associated sample text.

LaserWriter II Family: List Of Pinouts (6/94)

Revised: 6/23/94
Security: Everyone

LaserWriter II Family: List Of Pinouts (6/94)

Article Created: 15 January 1988
Article Reviewed/Updated: 23 June 1994

TOPIC -----

Is there a listing of the pinouts for the various connectors on the LaserWriter II I/O boards?

DISCUSSION -----

Here is a list of LaserWriter II I/O board pinouts:

LaserWriter II Mini Circular-8 RS-422:

Pin	Signal	Description
1	HSKo	Handshake output
2	HSKi	Handshake input
3	TxD-	Transmit data -
4	SG	Signal Ground
5	RxD-	Receive data -
6	TxD+	Transmit data +
7	RxD+	Receive data +

LaserWriter II RS-232C:

Pin	Signal	Description
1,7 *	SGnd	Signal Ground
2 *	Txd	Transmit Data
3 *	Rxd	Receive Data
4	Rts	Request to send
5	Cts	Clear to send
6	DSR	Data Set Ready

8	DCD	Data Carrier Detect
20	DTR	Data Terminal Ready
22	Ring	Ring indicator

* Only pins 1 (or 7,) 2, and 3 are needed by the LaserWriter II. The other pins exist for support of communication with devices requiring specific hardware handshaking.

NOTE: The RS-232C connector on the LaserWriter is configured as Data Terminal Equipment (DTE), which means that you can connect it directly to a modem or host computer that is configured as Data Communication Equipment (DCE) without any signal reversals. Connection to another DTE device, such as a Macintosh or IBM-compatible, requires that the TxD and the RxD of each connector be crossed connected.

LaserWriter IIsc, IIIntx, IIIf and IIg SCSI port:

Pin	Signal
26	/DATA0
27	/DATA1
28	/DATA2
29	/DATA3
30	/DATA4
31	/DATA5
32	/DATA6
33	/DATA7
34	/PARITY
38	+5V
41	/ATN
43	/BUSY
44	/ACK
45	/RST
46	/MSG
47	/SEL
48	C/D
49	REQ
50	I/O

Pins 1-12, 14-25, 35-37, 39, 40, 42 are GROUND. Pin 13 is not connected.

Apple DeskTop Bus Mini Circular-4:

Pin	Signal	Description
1		Bi-directional Data
2		Not Connected
3		Not connected
4		Ground

LaserWriter IIg ethernet connector:

Pin	Signal	Description
1	FN Pwr	Power (+12V @ 2.1W or +5V @ 1.9W)
2	DI-A	Data In circuit A
3	DI-B	Data In circuit B
4	VCC	Voltage Common
5	CI-A	Control In circuit A
6	CI-B	Control In circuit B
7	+5V	+5 volts (from host)
8	+5V	Secondary +5 volts (from host)
9	DO-A	Data Out circuit A
10	DO-B	Data Out circuit B
11	VCC	Secondary Voltage Common
12	NC	Reserved
13	NC	Reserved
14	FN Pwr	Secondary +12V @ 2.1W or +5V @ 1.9W
Shell	Prot Gnd	Protective Ground

LaserWriter IINT or IINTX: Description of Serial Communications

Revised: 9/15/93
Security: Everyone

LaserWriter IINT or IINTX: Description of Serial Communications

=====

Article Created: 15 January 1988
Article Reviewed/Updated: 15 September 1993

The LaserWriter IINT or LaserWriter IINTX has two serial channels, RS-422 and RS-232C. Either channel can be used for asynchronous serial communication. The RS-422 can also be used for synchronous communication for AppleTalk but NEVER for both serial and AppleTalk simultaneously.

Each channel sends and receives serial data encoded in ASCII. Both serial ports are enabled; they can be configured with independent data transmission rates and parity. The first channel to receive a character will execute the print job; if characters are also received on the alternate channel they are buffered, and on completion of the initial job will be executed.

CAUTION: Do NOT hook up AppleTalk and the RS-232C interface at the same time on the LaserWriter. If you use the RS-232C port, and leave AppleTalk connected on the LaserWriter IINT or LaserWriter IINTX, you must set the baud rate parameter for the RS-422 port to 0 (zero).

Changing Communication Parameters:

Many of the communication parameters can be changed by setting the hardware switches on the LaserWriter. Parameters controlled by these switches can also be changed by sending a PostScript program to the printer.

The hardware-controlled parameters and those that can not be configured by the hardware switches are stored in non-volatile memory (EEROM or ZPRAM) as system parameters, and are accessed through the special dictionary, "statusdict". To change the parameters, you must exit the normal server mode, and a password is required. Send the following program to LaserWriter:

```
serverdict begin password exitserver
statusdict begin channel baud options setscbatch
```

Where channel designates which serial port is to be configured, baud sets the baud rate, and options encodes the settings for parity, flow control, number of

data bits, and number of stop bits.

NOTE: When using the Diablo emulation mode, replace setsccbath with setsccinteractive.

Access II: Making room for more data on the backup disk

Revised: 5/25/89
Security: Everyone

Access II: Making room for more data on the backup disk

=====

To free up some disk space on your Access II diskette, use your BACKUP disk ONLY!

If you use the 80 column format, delete the following files from your backup disk:

UT40.SYSTEM
ACS40.SYSTEM
CON40

While these deletions make this disk unusable for the 40 column format, you now have about 104 more blocks you can use for saving downloaded files or captured data.

Deleting these files:

UT80.SYSTEM
ACS80.SYSTEM
CON80

from the backup disk frees up space for the user of the 40 column format and makes the disk unusable for the 80 column format.

To make the disk reusable for the format you deleted, simply copy the deleted files from the master to the backup disk.

Using a Appleworks Database file with Word Juggler

=====

This procedure describes how to use an Appleworks Database file as a source for a Word Juggler print form. These procedures are for Word Juggler version 2.9 and Appleworks version 1.3 other versions may vary from these instructions.

1. Create a report format in Appleworks.
2. Print the report To a text file on disk option 6. You will be asked for a Pathname. Enter (Data.File) as an example. Do not use the name of the Appleworks data file.
3. Exit Appleworks.
4. Start up Word Juggler.
5. Select 1 for new document.
6. Enter the information in the following format.
*number of fields
field name 1
field name 2
...other fields
Name of the file created in Appleworks example (Data.File).
All lines must end with a carriage return.

EXAMPLE
*5
name
address
city
state
zip.code
Data.File

7. Store the file as Field.List for example.
8. Select 1 for new file.
9. Create your form letter.
10. After you have finished creating the form letter store it to disk.
11. Select print form Closed-Apple-2.
12. Select Word Juggler Data file option 1.
13. For Pathname enter Field.List for example.

14. Word Juggler will now print your form letter using the data from Appleworks.

Notes

Use one disk if possible for the three files.

Variable names used in field.list and the form letter must be an exact match.

An example- name, Name & NAME are different.

FILE NAMES USED	DESCRIPTION
Data.File.....	file generated by Appleworks report containing data for the form letter.
Field.List.....	Interface file from Data.File to form letter. Created in Word Juggler.
form letter.....	Word Juggler form letter.

Hard Disk 20: Cable length limit with Macintosh

Revised: 10/12/87
Security: Everyone

Hard Disk 20: Cable length limit with Macintosh

=====

This article last reviewed: 17 May 1986

A cable 30 inches long may safely connect a Macintosh to an HD 20 as long as there is shielding integrity in the cable and connection. Any poor connections, flat cables, unshielded cables, or exposure to external EMI or RFI sources may affect operation. Cable lengths exceeding 30" are not recommended because of the excessive cable capacitance and IR drops.

Macintosh: 128K ROM Debugger

Revised: 8/26/86
Security: Everyone

Macintosh: 128K ROM Debugger

=====

The Macintosh Plus or any Macintosh with the 128K ROM's has a built-in debugger, a very limited tool compared to Macbug or any other advanced debugger.

Here are the commands:

G - The Go command with no parameter it will start execution at PC.
You can also have execution started anywhere by typing 'G XXXXXX',
where XXXXXX is the address you want it to start at.

DM XXXXXX - will display memory values starting at XXXXXX.

SM XXXXXX XXXX - will set memory location XXXXXX equal to value XXXX.
Note : You can include a string of values and they will
go into sequentially higher memory locations.

PC XXXXXX - will set the current program counter to XXXXXX.
NOTE : Issuing the PC command without a value prints the
current PC Value.

Ax - prints out the current value of Address register x.

Dx - prints out the current value of data register x.

Ax XXXXXX - sets Address register x to value XXXXXX.

Dx XXXXXX - sets Data register x to value XXXXXX.

Here are a few tricks:

To determine which ROM version you are using via the mini-monitor:

1. Press the interrupt switch on the programmer's switch to enter the built-in mini-monitor.
2. Type DM 400000. If the third byte value displayed is EA, it means

the revised ROMs; if it's EE, it means the original 128K ROMs.

3. Type G to return.

To return to the shell, type 'SM 15000 A9 F4', then 'G 15000'. This will usually get you back to the Finder.

Macintosh Interrupt

Revised: 7/20/92
Security: Everyone

Macintosh Interrupt

=====

Article Created: 20 May 1986
Article Last Reviewed: 17 July 1992
Article Last Updated:

PROBLEM DESCRIPTION: Customer has purchased the Macintosh 800K Enhancement or Macintosh Plus Upgrade and notices that when pressing "Interurrupt" on the Programers Switch a ">" appears in a dialog box. The prompt and dialog box did not appear on the customers Macintosh 512K before the upgrade occured.

CAUSE: This is not a software or hardware failure, but an added enhancement made to ROM for programing purposes. Pressing the interrupt switch after booting to the "desktop" or executing a program will cause the Macintosh to drop into the Mini-Debugger.

CURE: To exit the Mini-Debugger type "G" and press "RETURN". This will allow the user to resume work without having to reboot the computer.

Apple IIf: Splitting the Case

=====

Article Created: 15 July 1986
Article Last Reviewed: 17 July 1992
Article Last Updated:

PROBLEM DESCRIPTION: Using the normal Take-Apart section for splitting the Apple IIf case halves is difficult or nearly impossible to perform on some Apple IIf's that have never been taken apart before.

BEFORE YOU START: Familiarize yourself with the Apple IIf Take-Apart procedure (in Apple IIf Technical Procedures). Also, refer to Macintosh Technical Procedures to become familiar with using the Macintosh Take-Apart Tool. (Note: Apple IIf Technical Procedures will be revised to reflect this procedure.)

CURE: The Macintosh Take Apart Tool may be used to split the case halves of the Apple IIf. Insert the tool between the front case halves and spread them apart. Once you have the front end split apart try and work your way to the rear of the computer using the normal splitting procedure (see Apple IIf Take-Apart).

Hard Disk 20: Failure To Launch Application Or Format

Revised: 1/17/92
Security: Everyone

Hard Disk 20: Failure To Launch Application Or Format

=====

This article last reviewed: 28 March 1988

PROBLEM DESCRIPTION: Hard Disk 20 will not initialize media, or applications fail when launched. Also, sometimes application files will not transfer successfully to the Hard Disk 20.

BEFORE YOU START: Familiarize yourself with the Hard Disk 20 Owner's Manual and Hard Disk 20 Technical Procedures.

CAUSE: Hard Disk 20 controller board might contain a HAL instead of a PAL chip.

CURE: Check the serial number of the Hard Disk 20. If the serial number is F619xxx or higher, and the controller board contains a HAL chip at board location C3 (PAL is 16R6 is silk screened next to the chip), remove and replace the Controller Board using a service spare. Reconnect and power-up the Hard Disk 20. Try to initialize the drive. If initialization fails, refer to the Hard Disk 20 Technical Procedures for more troubleshooting information.

Super Serial Card: Blown Resistor

Revised: 1/17/92
Security: Everyone

Super Serial Card: Blown Resistor

=====

This article last reviewed: 28 March 1988

PROBLEM DESCRIPTION: ImageWriter causes R7 on the Super Serial Card to fail.

BEFORE YOU START: Familiarize yourself with the procedure for removal and replacement of the carrier drive transistors, referring to the ImageWriter Level I Technical Procedures.

CAUSE: One of the carriage transistors in the ImageWriter is shorted.

CURE: Follow these steps:

1. Remove the string of 4 carrier drive transistors and their associated insulators using the procedure documented in the ImageWriter Technical Procedures.
2. Check to make sure that none of the insulators is missing or cracked.
3. If any of the insulators is missing or cracked, replace them, reinstall the string of carriage transistors, and test the printer with the Super Serial Card. Otherwise, proceed to Step 4.
4. Replace the string of carriage transistors with a new set and test the printer using the Super Serial Card.
5. If the above procedure does not cure the problem, refer to Troubleshooting in the ImageWriter Technical Procedures.

Pascal Profile Manager (PPM): Using it with Pascal 1.3

Revised: 1/20/87
Security: Everyone

Pascal Profile Manager (PPM): Using it with Pascal 1.3

=====

Pascal Profile Manager (PPM) does work under Pascal 1.3.

Replace the following files with the 1.3 equivalent: SYSTEM.APPLE, SYSTEM.PASCAL, and SYSTEM.ATTACH. Moreover, since CHAINSTUFF 1.2 doesn't work with Pascal 1.3, it's a good idea to use the 1.3 SYSTEM.LIBRARY.

The only problem with PPM and 1.3 is not being able to use the X)tended filer, although its functions can be duplicated by using the F)iler for normal stuff and then X)ecuting PPM.CODE for the extra functions.

The most recent version of Backup II, version 1.1.1, fully supports 3.5 disks for backing Profiles and works well with disks containing Pascal Areas.

Backup II 1.1.1 is available on many consumer information services (e.g. CompuServe, Source, Genie, etc.).

Apple Pascal 1.3 and the Pascal Profile Manager are not compatible with the SCSI drive, the Apple HD20 SC. We are not aware of any existing software driver to allow Apple Pascal 1.3 to recognize the HD20 SC.

LaserWriter: Printing a square box

Revised: 7/18/86
Security: Everyone

LaserWriter: Printing a square box

=====

While making documents such as questionnaires, you might want to put in a square box for a check mark or some other response from your reader.

You can get a suitable box with a LaserWriter Plus from the lowercase "n" of the Zapf Dingbats font in the Outline style. A source for Zapf Dingbats is the LaserWriter and LaserWriter Plus Fonts Disk. You can find other "square box" key stroke alternatives by using the new Key Caps desk accessory.

A regular LaserWriter doesn't have the fonts that will allow you to print any sort of square box.

There is a work-around for this. You can modify an existing font to display and print a "square box" without having to purchase special third-party software. This work-around does not work around the problem when you have "Font Substitution" checked in "Page Setup" of the "File" menu.

1. Before you begin this procedure, check to make sure you have the following copies of these files:
 - a. A copy of ResEdit (available on CompuServe or in the Software Supplement)
 - b. A copy of your "Laserized" System File with Monaco font

The importance of working with copies cannot be overstated. Make sure that you start with a copy of your System File and a copy of the ResEdit program. ResEdit can cause havoc with your System File and corrupt data on your floppy or hard disk if used incorrectly.

2. "Open" the following files by double-clicking on the respective Icon in the order indicated below.
 - a. ResEdit
 - b. System Folder (If your System Files are in the System Folder)
 - c. System File
 - d. "Font"
 - e. Font named "Monaco 12"

After you have the Font "Monaco 12" opened, you may want to position the window to allow you to view the entire window by dragging the window to the center of the screen.

You now should have a large "a" on your screen.

3. Press the "[" key.

You can now modify the "[" by pointing and clicking the mouse where you need a "dot".

4. After you have finished modifying the "[" character into a box, simply close the windows one by one until you can quit from ResEdit.

Be sure to indicate "yes" when asked if you want to save changes to the System File.

Depending upon the size of your System File, the saving process may take some time. Be patient and don't interrupt this process.

To put the square in your document, select Monaco font (12pt) and press the "[" key. Be sure to turn off font substitution in "Page Setup" of the "File" menu before you have the document printed by the LaserWriter.

Macintosh 512Ke: Specifications (Discontinued) (8/94)

Article Created: 18 July 1986
Article Reviewed/Updated: 2 September 1994

TOPIC -----

This article gives the technical specifications for the Macintosh 512K enhanced computer.

DISCUSSION -----

MICROPROCESSOR

- Motorola MC68000, 32-bit architecture, 8 (7.8336) MHz clock speed

MEMORY

- 512K of RAM (Random Access Memory)
- 128K of ROM (Read Only Memory)

DISK DRIVE

- One built-in 800K disk drive. (Optional external 400K or 800K disk drive.)

SCREEN

- Built-in 9-inch diagonal, 512 by 342-pixel high-resolution bit-mapped monochrome display

INTERFACES

- Mouse port, DB-9 connector
- One eight-bit keyboard bus, 300 baud, RJ11 connector for Macintosh keyboard
- Two RS-232/RS-422 serial ports, 230.4K baud maximum (up to 0.920 Mbit per second if clocked externally), DB-9 connectors
- External Disk Drive interface (400K or 800K disk drives)
- Sound port for external audio amplifier or headphones

CLOCK/CALENDAR

- CMOS custom chip with 4.5 volt battery backup (Eveready No. 523 or

equivalent)

ELECTRICAL REQUIREMENTS

- Line voltage: 105 to 125 volts AC
- Line frequency: 50 to 60 hertz
- Maximum power: 60 watts

ENVIRONMENTAL REQUIREMENTS

- Operating temperature: 50 to 104 degrees F (10 to 40 C)
- Storage temperature: -40 to 122 degrees F (-40 to 50 C)
- Relative humidity: 5% to 90% relative humidity
- Altitude: 15,000 feet (4615 meters)

SIZE AND WEIGHT

- Height: 13.5 inches (34.6 cm)
- Width: 9.7 inches (24.6 cm)
- Depth: 10.9 inches (27.6 cm)
- Weight: 16 lb. 8 oz. (7.5. kg)

Logo II: Clearing an Apple IIc screen under Catalyst 3.0

=====

After loading LOGO II on an Apple IIc with Quark's Catalyst 3.0, the LOGO II screen is not cleared. You see High-Res graphic 'garbage' on the screen.

To solve the problem, simply execute the following command at the '?' prompt.

```
? .DEPOSIT 49247 0
```

This will clear the graphics left over from the Catalyst High-Res screen images.

LaserWriter: Defaults

Revised: 7/18/86
Security: Everyone

LaserWriter: Defaults

=====

This article last reviewed: 18 July 1986

The LaserWriter picks up its default settings, such as tall orientation, from the printer driver. To bring up a document with settings different from the default, such as wide orientation, create a special "boilerplate" document with the settings you require. Once you change the defaults, the new configurations are stored with the document when you save it. This method gives you much more versatility and is much easier than using RESEDIT to change the driver.

From then on, open that same document for those printer settings; they will automatically set to those stored with the document. Then use the "Save AS" option and save the document with a new name, which will preserve the original for the creation of more documents with those special settings.

LaserWriter: Driver errors

Revised: 8/10/87
Security: Everyone

LaserWriter: Driver errors

=====

An "Error in PostScript" message means that there is an error in the code generated in the driver that Apple has written. The error messages, generated by the application, would vary with the application.

Here is a list of the Printer Manager errors:

Error Value	Description
0	No error
128	Abort the printing process
-1	Problem saving print file
-17	Unimplemented control instruction
-27	Trouble with I/O
-108	Not enough heap space

The following errors are relevant to the LaserWriter ONLY.

-4101	Printer closed or not found
-4100	Connection just closed
-4099	Write request too big
-4098	Request already active
-4097	Bad connection refNum
-4096	Ne free Connect COntrol Blocks available

Page 110-111 of the Postscript Language Reference Manual gives a listing of the error messages that reside in the LaserWriter in the errordict.

AppleWorks: Recovering files after program hangs

Revised: 7/18/86
Security: Everyone

AppleWorks: Recovering files after program hangs

=====

The following procedure should be considered with these cautions:

1. DON'T KEEP USING APPLEWORKS AFTER YOU HAVE COMPLETED THIS PROCEDURE!
2. When this procedure works, the only thing you should do is save the files you were working on. This is intended as a Rescue Routine only.
3. This procedure does not ALWAYS work. Its reliability rate is about 95%. It can be unpredictable.

ALWAYS backup your work during every session!

The Procedure

It is actually very simple to get back into AppleWorks after the program hangs, no matter what the problem is. However, if the problem causes AppleWorks to crash into the monitor, then this procedure will probably be less reliable because such a problem could make further trouble. But if the only thing wrong happens to be that you have hung up the program to the point where the only escape is to hit control-reset to reboot, then this procedure is effective.

1. After hitting control-reset, the screen goes to 40 column mode, and you are left with the '*' prompt on the screen.

2. Type:

C073:0

and a CR. This will make sure that bank 0 of memory is selected.

3. Type:

3 CTRL-P

and a CR

Here are the keystrokes for that sequence:

- a. 3
- b. Hold down the control key while typing a 'P'
- c. RETURN

This SHOULD clear the screen, select 80 column mode, and put the prompt in the upper left hand corner of the screen. If it does, go on to step 4.

If this does NOT happen, type:

FF59G

and a CR

Then try 3 CTRL-P again. If this works, go on to step 4. If it does not, you will have to reboot.

4. The following line must be typed carefully and exactly as shown:

2F0:2C 83 C0 2C 83 C0 4C 33 10

and a CR

5. Next and last, type:

2F0G

and a CR

At this point, you should have the AppleWorks main menu back, and files that were on the desktop should still be there.

Do not continue work with any files. Save the files off the desktop and re-boot AppleWorks.

Sometimes the choices on the main menu will be numbered 7-12 or 11-16 instead of 1-6. This is not serious. Just flip back and forth between menus, such as selecting 'add files' then hitting ESC to go back, and the numbering should return to normal.

Macintosh: Converting Macintosh XL AppleTalk Connectors

Revised: 7/17/92
Security: Everyone

Macintosh: Converting Macintosh XL AppleTalk Connectors

=====

Article Created: 18 July 1986
Article Last Reviewed: 2 July 1992
Article Last Updated: 2 July 1992

To convert Macintosh XL Appletalk connectors to Macintosh (Mini-8) Appletalk connectors, follow the diagram below. Test the pin signals for each wire because the color coding may not be consistent.

DB-25 Mac XL	Color	Mini-8 Macintosh
2 TX-	green	3 TX-
3 RX-	white	5 RX-
19 RX+	blue	8 RX+
20 TX+	red	6 TX+

Other suggestions:

- Cut the cable about 3/8" up from the 25 pin connector so you can strip it back and verify the pinout- you'll need an ohmmeter or a continuity tester.
- Tin wires and connectors beforehand, of course.
- Use a soldering iron with a small tip and controlled temperature.
- Solder quickly so as not to deform the connector then clean with a good flux remover.
- First slide the outer plastic piece over the wire. Next fan the braid around the OUTSIDE of the metal shell and clamp it between the metal shell and the hard plastic pieces, then force the outer plastic piece over the whole connection.

Macintosh 64K and 128K ROMs: Startup Differences

Revised: 9/11/92
Security: Everyone

Macintosh 64K and 128K ROMs: Startup Differences

=====

Article Created: 15 August 1986

Article Change History

09/07/92 - REVISED

- For clarity and relevance. Focused article on Mac 512K since it's the only Macintosh to which this article applies.

09/07/92 - RETITLED

- Changed title to reflect new focus of article.

TOPIC -----

How can I tell what ROMs a Macintosh 512K has? What are some differences that I can see without looking at the logic board?

DISCUSSION -----

The 64K ROMs and 128K ROMs have different ways of starting up and looking for the System file on a disk.

To tell if your Macintosh 512K has 64K or 128K ROMs, check either of the following:

1. Choose "About the Finder" in the Apple Menu. At the bottom left corner of the box that appears, the amount of RAM (in K) that the Macintosh has will be displayed.
 - a. A K without a period following it indicates the 64K ROMs.
 - b. A K with a period following it indicates the 128K ROMs.
2. Look at the title bar of any window.
 - a. Windows with only a close box in the title bar indicate the

64K ROMs.

- b. Windows with a close box and a resize or zoom box in the title bar indicate the 128K ROMs.

Now that you can identify which ROMs are in your Macintosh, here's how each type boots:

1. Macintosh 512K with 64K ROMs

The startup procedure looks first at the internal floppy drive and then the external drive. If the Macintosh does not find the System file on a disk in the internal drive, it ejects the disk there and looks to the external drive. If there is no system file on the disk in the external drive, that disk is also ejected.

The Hard Disk 20 Startup disk in the internal drive will load the HFS file system and drivers into memory and eject the disk if there is a system folder on the HD 20.

2. Macintosh Plus or Macintosh 512K Extended with 128K ROMs

The startup procedure looks for a valid system folder in these devices in the following order:

- a. Internal floppy disk drive
- b. External floppy disk drive
- c. Hard Disk 20 (System Folder)
- d. SCSI devices

Apple IIfc Technical Procedures: Erratum

Revised: 11/10/88
Security: Everyone

Apple IIfc Technical Procedures: Erratum

=====

This article last reviewed: 10 November 1988

On page 2.9 of the Apple IIfc Technical Procedures, Apple IIfc Diagnostics, the second sentence states that you can boot from the external drive in order to test that drive.

However, if you have an Apple IIfc with the logic board upgraded with new ROMs and you attempt to boot it from the Apple IIfc External 5.25" Drive, you get the message "AppleTalk Off-Line".

New or upgraded Apple IIfc systems configure an Apple IIfc External 5.25" Drive as a second drive, which cannot be used for a boot, as in the Apple IIe. Typing "PR#5" will just cause the system to hang, since the External 5.25" Drive is now considered to be Drive 2 of Slot 6. Typing "PR#7" will produce the "AppleTalk Off-Line" message.

You can, however, boot such a system from a 3.5" drive with a "PR#5" because new or upgraded Apple IIfc systems configure the 3.5" drive as a first drive, Drive 1 of Slot 5, which can be used for a boot, as in the Apple IIe.

Apple Personal Modem: Carrier detect

Revised: 8/3/89
Security: Everyone

Apple Personal Modem: Carrier detect

=====

Some software packages, such as Dow Jones Market Manager Plus, don't appear to get a carrier detect because the Apple Personal Modem's 0.6 seconds of carrier detect response time is not enough time for the hookup of the software. Carrier detect response time, register S9 on the APM, cannot be changed.

To workaroud this situation, you must send a command to adjust the Carrier Wait register, S7, to tell the modem how long to wait for a carrier. The command is ATS7x, where x has a range of 1 to 255. For example, to reset the default Carrier Wait, 30 seconds, send the command ATS730.

LaserWriter Plus: Diagnostics

Revised: 11/10/88
Security: Everyone

LaserWriter Plus: Diagnostics

=====

This article last reviewed: 10 November 1988

The Technical Procedures do not make it clear that no message will be returned if the diagnostics find that the ROMs are OK. The LaserWriter Plus diagnostics are contained in ROMs H3 and L3 (board locations E7 and F7).

If all the ROMs are OK, nothing will be printed from the diagnostics. If an error is found, then an error message will appear on the Macintosh screen.

The Technical Procedures are being updated to reflect this fact.

LaserWriter: Test page in Special mode

Revised: 6/18/86
Security: Everyone

LaserWriter: Test page in Special mode

=====

A test print will occur in the "Special" switch setting of a LaserWriter or LaserWriter Plus, contrary to some sources, such as page 130 of the manual for the LaserWriter and LaserWriter Plus.

The line graph on the test print shows two tick marks on the x-axis. These tick marks indicate Special mode. The bar graph on the test print shows which port is active at which baud rate. For example, if the 25-pin port is active at 9600 baud, then above the number 25 on the graph's x-axis, there is a bar extending up to the number 9600 on the y-axis.

Macintosh: Transferring information to and from an Apple III

Revised: 3/22/88
Security: Everyone

Macintosh: Transferring information to and from an Apple III

=====

This article last reviewed: 20 June 1986

To transfer information between an Apple III and a Macintosh, use Access III on the Apple III and MacTerminal on the Macintosh. To connect an Apple III to Macintosh Plus, use the peripheral adapter cable and the Macintosh 512K to ImageWriter I cable (590-0169).

If using the Apple III serial card, have the card set to no - modem eliminator. If using the built-in port C, make sure you're using the .RS-232 driver rather than the .PRINTER driver. You can find the .RS-232 driver for the built-in port C on the System Utilities Data diskette.

Make sure both systems are set for the same baud rate, data bits, and so forth, and then simply set one system up to send a file and the other one to receive a file.

Apple II Machine Language: Accessing the keyboard

Revised: 6/9/86
Security: Everyone

Apple II Machine Language: Accessing the keyboard

=====

When writing a machine language routine to check the keyboard for a single character, make sure that the routine checks for the high bit at the keyboard, signifying valid data, before the routine attempts to read data there.

Here is an example of such a routine:

```
ORG    $300
KBD     EQU    $C000      ; location of keyboard data
KBDSTRB EQU    $C010      ; location of keyboard strobe latch

ReadKey  BIT    KBD        ; test high bit of data reg.
        BPL    ReadKey    ; If not set retest till it is set
        LDA    KBD        ; Data at KBD is Valid (High Bit set)
        BIT    KBDSTRB    ; now clear the keyboard for the next char
        RTS              ; and we are done.
```

The act of striking a key will set the strobe bit automatically, so this routine clears it before returning.

If you are testing for a particular keystroke, put the test in a separate routine. Here is an example of how that would be done:

```
...
        BIT    KBDSTRB    ; Clear out any data that is already at KBD
WaitForA JSR    ReadKey    ; get a key from the keyboard
        CMP    #$C1       ; is it an A????
        BNE    WaitForA   ; Nope go get another
        RTS
...
```

These methods apply to all Apple II's: II, II Plus, IIe, IIe enhanced, and IIC.

LaserWriter IINT: Controller Description

=====

Articel Created: 15 January 1988
Article Reviewed/Updated: 15 September 1993

The LaserWriter IINT controller consists of:

- MC68000 (11.16 MHz)
- 2 megabytes of RAM
- 1 megabyte of ROM (rev 47 PostScript)
- a two-position DIP switch for serial port configuration

It supports AppleTalk and serial communications over aDB-25 RS-232 and a mini-8 RS-422 ports. The Apple DeskTop Bus port has been added for future enhancements, but it is not supported in this version of the ROM.

AppleWorks: Using an ImageWriter II's sheetfeeder

Revised: 6/5/86
Security: Everyone

AppleWorks: Using an ImageWriter II's sheetfeeder

=====

An ImageWriter II doesn't print more than 11 inches on legal size (14-inch) paper fed through the sheetfeeder.

Workaround:

1. From AppleWorks, identify the ImageWriter II as a custom printer.
2. Under printer codes, select either subscript or superscript begin.
3. Insert an ESCAPE H 2016.

The H must be a capital H. The code ESCAPE H 2016 sets the form length to 14 inches (in increments of 1/144 of an inch).

4. At the top of the document, by typing the open-Apple O command and the appropriate code:
 - a. Insert the subscript or superscript begin, whichever you used in step 2
 - b. Set the page length to 14 inches.

You should be able to print legal size documents from this AppleWorks setup using the sheet feeder on the ImageWriter II.

The problem has been passed on to the product engineer.

Macintosh 512K ROM Upgrade: Memory Available

Revised: 5/11/89
Security: Everyone

Macintosh 512K ROM Upgrade: Memory Available

=====

The upgrade makes a negligible difference of 1.5K in available memory over the 372K available on the original Macintosh 512K. This is the result of the combination of more system stuff and an increase in the system heap for global variables.

The benefit of the 128K ROMs is in the increased speed in performing rote functions: opening and closing windows, redrawing, and accessing the faster ROM-based routines instead of the slow RAM-based routines.

LaserWriter IINT: Switch Configurations

Revised: 9/15/93
Security: Everyone

LaserWriter IINT: Switch Configurations

=====

Article Created: 15 January 1988
Article Reviewed/Updated: 15 September 1993

The LaserWriter IINT has a two-position DIP switch located on the controller panel. This switch is used for controlling the mode of operation, serial port configuration, and communication parameters.

Switch 1	Switch 2	Meaning
Up	Up	AppleTalk (Serial Port Disabled)
Down	Down	RS-232 and RS-422 * Serial Ports 1200 baud
Up	Down	RS-232 and RS-422 * Serial Ports 9600 baud
Down	Up	Special Diablo 630 emulation

* BOTH serial ports are enabled. Serial communication and AppleTalk communication are NOT compatible and will never occur at the same time.

These serial port configurations are stored in the EEROM as persistent parameters, and can be overridden by downloading a PostScript program. The EEROM configuration is updated to match the switch configurations if:

- the switches are changed between a power-off/on cycle
- or
- the switch settings do not match the values in EEROM at start-up
- or
- while the printer is on you toggle a switch, wait 30 seconds, and toggle it back.

Other asynchronous configurations of the SCC ports are available. Refer to the current Apple LaserWriter reference manual or the current PostScript Language

..TIL01992-LaserWriter_IINT-Switch_Configurations_(TA35606).pdf

reference manual for information on setting the parameters of the serial ports.

ImageWriter II: IBM 3287 printer emulation

Revised: 8/3/89
Security: Everyone

ImageWriter II: IBM 3287 printer emulation

=====

This article last reviewed: 4 June 1986

ImageWriter II's make good replacements for the IBM 3287 dot matrix printers commonly used with the IBM 3270 family of terminal devices. The IBM 3278 terminals can be replaced with an AppleLine-Macintosh-MacTerminal combination, and you can replace the IBM 3287 printers with this simple and cost effective configuration:

Equipment	Vendor	Number
-----	-----	-----
IRMAprint	DCA *	PC3287-S
ImageWriter II Printer	Apple	A9M0310
Apple II Printer 8 cable	Apple	A9C0313

--> Installation Diagram

IBM 3274/6 --> Coax cable --> IRMAprint --> Printer 8 cable --> ImageWriter II

This solution proves to be a good value because it provides better print quality and speed than the IBM 3287 or similar printers such as Telex.

Mini-Circular 8 pin connector sources

=====

Article Created: 2 June 1986
Article Last Reviewed: 15 June 1992
Article Last Updated:

TOPIC -----

Who else makes connectors that are compatible with mini-circular 8 pin connectors used on the Mac Plus?

DISCUSSION -----

For the 8 pin mini-circular connectors used on the Macintosh Plus, Apple Personal Modem, and ImageWriter Plus, there are two vendors of connectors which have pins that conform to the Apple specification for length and diameter:

1. "C" Enterprises

Wiring connection: Machine-attach pin

2. AESP (Advanced Electronic Support Products - formerly Roman Cable)

Wiring connection: Female pin, which makes soldering easier for the user.

AESP connectors have the same construction and assembly as the AppleTalk Custom Cable Kit connectors.

For more information search on "C" Enterprises or AESP.

Security: Everyone

800K Floppy Drives: Don't Use with Old Hewlett-Packard 3.5 Disks

=====

This article last reviewed: 10 November 1987

A word of caution to those who try to use the old HP 3-1/2" disks (i.e., the ones that don't have springs; you have to open and close the shutter by hand) in the 800K Macintosh and UniDisk 3.5 drives.

An old HP disk has a protective door which locks in the open position when it is opened all the way. An Apple 400K drive doesn't slide the door all the way open, and so it doesn't lock in the open position.

However, an Apple 800K drive does slide the door all the way open, and because the protective door locks, the drive isn't able to eject the disk.

Macintosh Plus: Hanging on Boot and ROM versions (8/95)

Article Created: 29 May 1986
Article Review/Updated: 23 August 1995

TOPIC -----

My Macintosh Plus hangs at startup intermittently. I'm not sure why, any ideas?

DISCUSSION -----

When a Macintosh Plus hangs on boot, check for a connected SCSI device that is powered off. If such a device is connected, the Macintosh Plus may have the original 128K ROMs that have this problem, which was corrected in the revised ROMs.

Workaround:

Power up the SCSI device or disconnect it.

There are two methods that can be used to check the ROM version on a Macintosh Plus: the serial number and the built-in mini-monitor.

1. Serial number

A factory built Macintosh Plus computer with a serial number beyond F609xxxMxxxxx has the revised ROMs. However, if you are not sure if your machine was upgraded to a Macintosh Plus, or if you have a serial number earlier than that, move on to the next method.

2. Mini-monitor

Follow these steps to use the mini-monitor to check ROM version:

Step 1

Press the interrupt switch on the programmer's switch to enter

the built-in mini-monitor.

Step 2

Type DM 400000. If the third byte value displayed is EA, it means the revised ROMs; if it's EE, it means the original 128K ROMs.

Step 3

C. Type G to return.

ALL upgrade kits were shipped with the revised ROMs.

Macintosh: Logic Boards May Mis-align with Programmer's Switch

=====

Article Created: 28 May 1986

Article Change History

09/07/92 - REVIEWED
• For technical accuracy

TOPIC -----

After I had my the logic board in my Macintosh IIcx upgraded, it behaves strangely and sometimes the sad Macintosh will show up at startup. What's going on?

DISCUSSION -----

After the installation of a logic board, a Macintosh's strange behavior or the appearance of the Sad Macintosh may stem from the improper alignment of the reset and interrupt buttons with the programmer's switch on the outside of the case.

Workaround:

Remove the progammer's switch, re-insert the programmer's switch, and check the alignment with the corresponding buttons on the logic board. If the problem persists, remove 1 millimeter of plastic from the ends of the two projections on the inside of the programmer's switch; these two ends contact the buttons.

LaserWriter IINTX and PostScript: A General Description

Revised: 5/3/89
Security: Everyone

LaserWriter IINTX and PostScript: A General Description

=====

This article last reviewed: 10 March 1989

The LaserWriter IINTX is an expandable printer. It is configured with:

- MC68020 (16. MHz) microprocessor
- 2 megabytes of RAM expandable to 12 megabytes
- 1 megabytes of ROM (rev 47 Postscript) expandable to 8 megabytes
- A bank of 6 DIP switches for serial port configuration, which can be set for Diablo 630 or LaserJet+ emulation
- A SCSI expansion port supported by the PostScript extensions for file systems

It supports AppleTalk and serial communications over a DB-25 RS-232 port and a mini-8 RS-422 port. The Apple DeskTop Bus port has been added for future enhancements, but is not supported in this version of the ROM.

	Printer with Controller	Controller Only
Marketing Number:	M6215	M6004

PostScript File System

On the LaserWriter IIntx, PostScript has been extended to include a simple file system. This file system provides support of non-volatile storage for:

- A cache of character bitmaps
- A user accessible file storage
- A display-list buffer (which stores compiled PostScript instructions.)

There are two types of devices supported by the file system:

- The disk device (or multiple disks forming one logical disk device), and
- The cartridge device (configured as additional ROM up to 8M.)

More information on the PostScript File System extension and its operators can be found in the current Apple LaserWriter reference manual and the current PostScript Language reference manual.

LaserWriter IIntx: RAM Expansion

Revised: 9/22/89
Security: Everyone

LaserWriter IIntx: RAM Expansion

=====

This article last reviewed: 15 January 1988

Adding RAM allows more fonts to be downloaded to the printer at any one time, and increases the space available for font caching. The additional RAM also lessens the need for reconstructing bitmaps.

RAM Expansion Kits

	1 Megabyte	4 Megabyte
Marketing Number:	M6005	M6006

(NOTE: These SIMM expansions CAN NOT be used in a Macintosh computer.)

RAM Configurations

There are three banks of RAM on the LaserWriter IIntx controller, each bank consisting of 4 SIMM sockets, which can be configured with four 256Kbyte SIMMs or four(4) 1Mbyte SIMMs. Bank 0, located farthest from the controller panel, must be configured with the largest size SIMM.

Manzanita Product Comparisons (1 of 2)

=====

Manzanita Software Systems specializes in high-quality business accounting software for the Apple II computer family. The following details the specifications of Manzanita's accounting products: The Business Accountant(R), and BusinessWorks(R). (This is part 1 of two parts.)

HARDWARE REQUIREMENTS

The Business Accountant:

Apple IIe or IIC
Two 5-1/4" floppy disk drives or one 5-1/4" floppy and a DOS 3.3 hard disk
Monitor
Printer

BusinessWorks:

Apple IIe or IIC
Two UniDisk 3.5 drives, or one UniDisk 3.5 drive and a RAM card, or one floppy disk drive (3-1/2" or 5-1/4") and a ProDOS hard disk.
Monitor
Printer

	The Business Accountant -----	BusinessWorks -----
System-Wide Features		
Operating System	DOS 3.3	ProDOS
On-line HELP	No	Yes
Show windows listing needed data	No	Yes
Password protection	Yes	Yes
Supports clock card	Yes	Yes
Modules integrate or stand-alone	Yes	Yes
Converts data to DIF	Yes	No
Converts data to AppleWorks	No	Yes
Uses AppleWorks filecard metaphor	No	Yes
Installs on Catalyst (2.0 and 3.0)	No	Yes

..TIL02008-Manzanita_Product_Comparisons_1_of_2_(TA35726).pdf

Works with Pinpoint	No	Yes
Loads on RAM cards	No	Yes
Accesses other software directly	No	Yes
Number of multiple companies:		
removable media disk	Unlimited	Unlimited
hard disk	1	50

General Ledger System

Maximum number of accounts	500	1,000
# of characters in acct. description	22	22
Maximum # of monthly journal entries:		
removable media disk	500-1,900*	20,000*
hard disk	2,300**	20,000*
Maximum amount for each j/e	\$9,999,999.99	\$9,999,999.99
# of recurring journal entries	15	15
# of account types	14	14
# of reports in report queue	8	8
# of months budgeted	12	12
# of months history maintained	13	13
# of departments	99	99
# of lines per journal entry	99	99
Maximum dollar amount	\$43 million	\$43 million
Rounds financial reports to nearest \$	no	yes
Posts to prior months in fiscal year	yes	yes
Posts to future months	no	yes

Accounts Payable System

Maximum number of vendors:		
removable media disk	500	1,000*
hard disk	6,320**	10,000*
Maximum number of transactions:		
removable media disk	1,750*	***
hard disk	16,000**	***
Distribution accts. per transaction	8	8
# of payment terms	9	9
# of characters in vendor ID	8	8
# of characters in invoice #	8	8
# of characters in invoice reference	12	12
Maximum amount per transaction	\$999,999.99	\$999,999.99
Maximum amount per check	\$999,999.99	\$999,999.99
Invoices per check	Unlimited	Unlimited
# of cash accounts	1	4
Reconcile checkbook	No	Yes
Check voiding	No	Yes
Recurring payable invoices	No	Yes
Open credits	Yes	Yes
Discounts	Yes	Yes
Prints check with register	Yes	Yes
Allows handchecks	Yes	Yes

*The actual maximum numbers may be less than those listed, depending on the

number of accounting modules you use, and/or the number of accounts, vendors, parts or customers on the system. These numbers should be used as general guidelines. Refer to the sizing worksheets for more specific information.

**These figures reflect using a DOS 3.3 hard disk with a maximum of eight data sets.

***Limited only by disk space.

Manzanita Product Comparisons (2 of 2)

=====

Manzanita Software Systems markets business accounting products for the Apple IIe and IIc. The following chart compares specifications of The Business Accountant and BusinessWorks. This is part 2 of two parts.

	The Business Accountant -----	BusinessWorks -----
Accounts Receivable System		
Maximum number of customers:		
removable media disk	500	1,000*
hard disk	5,840**	10,000*
Maximum number of transactions:		
removable media disk	2,320*	***
hard disk	20,800**	***
Maximum number of sales reps	n/a	16
# of customer notes	9	9
# of dunning notes	3	3
# of payment terms	9	9
# of sales accounts	8	16
# of sales tax jurisdictions	1	3
# of line items per invoice	16	40
Maximum invoice amount	\$999,999.99	\$80,000.00
# of characters in customer ID	8	8
# of digits in invoice number	5	5
Credit and open invoice inquiry	yes	yes
Includes contact names	no	yes
Prints invoices, debit, credit memos	yes	yes
Invoices directly from inventory	no	yes
Returns product to inventory	no	yes
Recurring receivables invoices	no	yes
Handles open credits	yes	yes
Calculates finance charges	yes	yes
Maintains customers' high balances	no	yes

..TIL02009-Manzanita_Product_Comparisons_2_of_2_(TA35735).pdf

Open item & balance forward statements	yes	yes
Sorts all reports by sales rep	no	yes

Inventory Control System

Maximum number of parts:

removable media disk	1,000*	1,000*
hard disk	10,000**	10,000*

Maximum number of transactions:

removable media disk	4,000	***
hard disk	38,400**	***
# of product groups	99	99
# of bins/locations	n/a	99
# of costing methods (LIFO,FIFO, standard, weighted average)	4	4
# of price levels	1	3
# of cost of goods sold accounts	8	16
Maximum on-hand quantity of any part	999,999	999,999.99
Maximum amount of purchase order	\$999,999.99	\$999,999.99
Global prices changes	no	yes
Fractional quantities	no	yes
Prints purchase orders	yes	yes
Retains purchase order detail	no	yes
Allows receipts & cancellations of p.o.'s	no	yes
Calculates inventory turnover	no	yes
Handles return of merchandise to inventory	no	yes
Maintains YTD sales and costs of goods sold	no	yes
Handles physical inventory	yes	yes

Payroll System

Maximum number of employees:

removable media disk	200*	500*
hard disk	300*	1,000*
Deductions	12	25
with company contribution	no	yes
Commissions	12	25
Overtime rates	3	3
Standard rates	50	100
Job codes	100	200
# of pay types	4	5
# of pay periods	4	4
Maximum individual annual earnings	\$999,999.99	\$999,999.99
Tax tables for 50 states, DC, federal	yes	yes
Multiple earnings categories	yes	yes
Compensation time	no	yes
Shift differentials	no	yes
Departmental posting	no	yes
Checks and handchecks	yes	yes
Retain check detail for quarter	no	yes
Void most recent checks	yes	yes

Void any check	no	yes
Labels Plus		
# of names in mailing list:		
removable media disk	1,000	1,000*
hard disk	8,000**	10,000*
Number of selection keys	8	8
# of label definitions	1	4
Maximum number of labels across	4	4
# of characters in ID	8	8
Minimum label width, in characters	24	24
Maximum label width, in characters	72	72
Minimum label height, in lines	4	4
Maximum label height, in lines	24	24
Name and address lists	yes	yes
Telephone lists	yes	yes
Mailing labels (roll or single sheet)	yes	yes
Merge vendors, customers & employees	yes	yes

*The actual maximum numbers may be less than those listed, depending on the number of accounting modules you use, and/or the number of accounts, vendors, parts or customers on the system. These numbers should be used as general guidelines. Refer to the sizing worksheets for more specific information.

ImageWriter Blows 5 AMP Fuse

Revised: 1/17/92
Security: Everyone

ImageWriter Blows 5 AMP Fuse

=====

This article last reviewed: 28 March 1988

PROBLEM DESCRIPTION: ImageWriter continues to blow 5 amp fuses on the CPU PCB.

BEFORE YOU START: Familiarize yourself with ImageWriter Technical Procedures.

CAUSE: Print head might be shorted.

CURE: Try the following steps and refer to ImageWriter Technical Procedures when needed:

1. Remove and replace the print head.
2. Replace the 5 amp fuse with a known good one.
3. Reassemble the printer.
4. Run the built-in "Self-Test".
5. If the 5 amp fuse blows again, refer to ImageWriter Technical Procedures for more information on troubleshooting.

Hard Disk 20: Applications Launch Slowly

Revised: 11/10/88
Security: Everyone

Hard Disk 20: Applications Launch Slowly

=====

This article last reviewed: 28 March 1988

PROBLEM DESCRIPTION: Customer complains that it takes an unusually long time to launch an application or boot from the Hard Disk 20.

BEFORE YOU START: Make sure that you are using Finder version 4.1 or greater.

CAUSE: The "Desktop" has been rebuilt or the media is becoming full. Performing the following steps will cause the files to be written to the drive in a sequential fashion, allowing faster access to data on that drive.

CURE: Perform the following procedure:

1. Make certain that the Hard Disk 20 and the computer are turned off.
2. Connect a newly formatted Hard Disk 20 to the disk drive port of the problem drive. If a Hard Disk 20 is not available, a floppy drive will suffice.
(Note: Some files might be too large to copy to a floppy.)
3. Power on the computer and both hard disks if you have not yet done so.
4. Select all Icons on the problem drive by using the "Select All" function from the "Edit" menu and move those files to the backup Hard Disk. If a floppy drive is being used as the backup drive, the files must be transferred individually.
5. Verify that ALL data has been transferred to the backup disk drive after the file transfer is finished.
6. If all data has been transferred properly, continue to s8-7. Otherwise retry steps 1-5.
7. Open the System folder on the backup drive and double-click on the "Finder" icon.
8. Close all windows so that only the two drive Icons show on the screen.
9. Highlight the icon of the problem drive and select "Erase" from the "Special" menu.
10. Open the backup drive icon and choose "Select All" from the "Edit" menu.

11. Move all files from the backup drive to the original "problem drive".

12. Select "Shut Down" from the "Special" menu and reboot the computer. Your applications should launch much faster. When booting from the Hard Disk 20 and using a Macintosh Plus or Enhanced Macintosh 512k, there should be a noticeable improvement in booting speed.

Lisa:10707 Error when Booting the Lisa Office Systems I Disk

=====

Article Created: 13 August 1986
Article Last Reviewed: 17 July 1992
Article Last Updated: 17 July 1992

PROBLEM DESCRIPTION: The 10707 Error occurs upon booting the Office Systems I disk or ProFile hard disk.

BEFORE YOU START: Familiarize yourself with the Lisa (or Macintosh XL) Technical Procedures.

CAUSE: The disk is write-protected or the system software is damaged.

CURE: To unprotect the disk, slide the write-protect tab so that it covers the small rectangular opening (see the Lisa or Macintosh owner's manual if you are not sure how to perform this procedure).

If using a ProFile, boot the Office System 1 diskette. Choose the "Repair" option. If this fails, choose "Install" and reinstall the Office System. If this still fails, back up the customer's data, reinitialize the ProFile using the Install option, and install the Office System.

ImageWriter II Paper Guide

Revised: 1/17/92
Security: Everyone

ImageWriter II Paper Guide

=====

This article last reviewed: 28 March 1988

PROBLEM DESCRIPTION: The new paper guides seem hard to install when using the old installation procedure documented in the ImageWriter II Technical Procedures manual.

BEFORE YOU START: Familiarize yourself with the ImageWriter II Technical Procedures.

CAUSE: Design changes made to the paper guide require a different method of installation. There are 2 different ImageWriter II paper guides. The NEW paper guide has a reinforcing bar molded to the bottom of the opening that is covered by the "metal foil". The older part does not have this reinforcing bar.

CURE: Remove the print head first before installing the new-style paper guide. See the ImageWriter II Technical Procedures for more information on how to install the paper guide. Then follow the normal paper guide procedure as documented in the ImageWriter II Technical Procedures.

ImageWriter II Print Quality

Revised: 1/17/92
Security: Everyone

ImageWriter II Print Quality

=====

This article last reviewed: 28 March 1988

PROBLEM DESCRIPTION: The ImageWriter II produces blurred print when used with the Macintosh in "high quality mode".

BEFORE YOU START: Familiarize yourself with the ImageWriter II Technical Procedures.

CAUSE: The wrong print driver might be installed (such as 2.2).

CURE: Install ImageWriter driver version 2.3 or higher.

OTHER POSSIBLE CAUSES/CURES: "Over inking" might occur when using a new ribbon with porous paper. The thickness lever might be adjusted too far forward. Some applications might require that an older driver be used.

Macintosh: Resources

Revised: 5/10/89
Security: Everyone

Macintosh: Resources

=====

This article last reviewed: 10 November 1987

Every Macintosh application is a collection of discrete modules of data called resources. When a programmer assembles or compiles his source code into object code, the code is placed in a resource of type CODE. The programmer may then link to his CODE resource other data resources his code will use. These may include resources such as menus, fonts, windows, controls, dialog boxes, icons or pictures.

At power up, the Resource Manager initializes in ROM. To refer to and access resources, which are grouped logically by "type", application code can use the Resource Manager on an "as needed" basis, usually specifying the resource by type and either ID number or name. Since resources can be contained in files separate from the programmer's CODE resource, many programmers keep their code size minimal by referencing resources in the System file.

Resource types are distinguished by their four-character labels. Apple has reserved all resource type names which consist of lower case or international characters (ASCII \$61-\$7A and \$7F on up). Additionally, Apple reserves the resource type names in the article "Macintosh: Reserved resource type names".

You can make alterations to discrete resources outside of the programmer's code, customizing or localizing the resource with foreign language prompts, currency formatting and other custom representations. Use ResEdit, REdit, and these tools' accompanying documentation, available through the Apple Programmer Development Association (APDA), to individualize almost any application or to edit custom-programmed resources.

For sources of information about the Resource Manager and resources in applications and in ROM, consult Inside Macintosh, volumes I-IV. Chapter 5, volume I and chapter 3 volume IV pertain directly to the Resource Manager. For information about resources used by the DeskTop file, read Apple Macintosh TechNote #29, "Resources Contained in the DeskTop File."

ImageWriter Carriage Assembly stops or vibrates

Revised: 1/17/92
Security: Everyone

ImageWriter Carriage Assembly stops or vibrates

=====

This article last reviewed: 28 March 1988

PROBLEM DESCRIPTION #1: The ImageWriter printer carriage assembly freezes or grinds when connected to a Macintosh or Apple II Super Serial card.

BEFORE YOU START: Familiarize yourself with the ImageWriter Technical Procedures.

CAUSE: One or more of the carriage drive transistors is defective or one or more of the insulators is cracked or broken.

CURE: Remove the string of carriage transistors from the ImageWriter referencing the technical procedures if needed. Check to make sure that none of the insulators is missing. Each transistor should have a mylar insulator between it and the printer chassis. An insulator for the screw should also be present. Install new insulators if any are missing or cracked. Reassemble the printer and run the printer self-test.

In the event that all insulators are in good condition then replace the string of carriage transistors. ALWAYS REMEMBER TO REINSTALL ALL INSULATORS WHEN THE CARRIAGE TRANSISTORS ARE REPLACED. REMEMBER THAT THE PRINTER WILL EXHIBIT THE SAME SYMPTOMS IF THE INSULATORS ARE MISSING. (A TRANSISTOR SHORTED TO GROUND.)

Run an extensive self test on the printer. Sometimes the CPU board will cause transistor(s) to fail again. In the event that this occurs, replace the CPU board and the transistor assembly.

PROBLEM DESCRIPTION #2: The Carriage Assembly stops or vibrates when powered on and the printer IS NOT connected to a computer.

CAUSE: Occasionally, one of the transistor wires is cold-soldered to the transistor itself.

CURE: Replace the string of carriage transistors.

ImageWriter II won't print from Macintosh

Revised: 1/17/92
Security: Everyone

ImageWriter II won't print from Macintosh

=====

This article last reviewed: 28 March 1988

PROBLEM DESCRIPTION: The ImageWriter II printer won't print when interfaced with the Macintosh and the printer has the 32K Option card installed. The ImageWriter does, however, perform a self-test with no errors.

BEFORE YOU START: Make sure that the print driver has been installed properly on the customers software then attempt to print to a known-good Imagewriter.

CAUSE: The Option card is bad (even though the self-test generates no errors).

CURE: Remove the 32K Option Card and test the printer with the Macintosh connected to the ImageWriter II. Boot a program such as MacWrite and print to the ImageWriter II. Swap the Option Card with a known good one and try to print with MacWrite again.

Refer to General Troubleshooting for the ImageWriter II if the printer still does not print.

Apple II ProFile Interface Card Modification for the Apple II GS

Revised: 1/17/92
Security: Everyone

Apple II ProFile Interface Card Modification for the Apple II GS

=====

This article last reviewed: 28 March 1988

PROBLEM DESCRIPTION: Some ProFile Interface cards will not work properly when installed in the Apple IIGS. ProFile directory information might become damaged and cause the user not to be able to access data stored on the ProFile.

CAUSE: There might be an incomplete ground path through the card.

CURE: If ANY ProFile Interface Card is to be installed in an Apple IIGS, check first to see that a jumper, made of 24-26 gauge multistrand wire is installed between pin 12 of IC C6 (2716 EPROM-Apple Part# 341-0299) and pin 1 of IC B4 (74LS368-Apple Part# 305-0368) on the non-component side of the board. If needed, the jumper should be installed by a knowledgeable technician to assure proper operation of the ProFile when interfaced with the Apple IIGS. The jumper wire should be just long enough to make the connection. The technician should remove the EPROM before soldering, thus preventing any damage to the chip.

Apple Personal Modem: Setting registers from Applesoft BASIC

Revised: 8/27/86
Security: Everyone

Apple Personal Modem: Setting registers from Applesoft BASIC

=====

To set the registers on the Apple Personal Modem from Applesoft BASIC, use this program, based on a program that sends custom characters to ImageWriters. Line 60 contains the machine language program that downloads commands. Line 70 contains the ASCII codes for the command string.

Line 70 of this particular example makes the program set the S0 register to 255 by sending the string ATS0=255 <RETURN>, a return the APM must have to accept the command string in all cases.

```
10 D$=CHR$(4)
20 FOR I= 768 TO 773: READ J : POKE I,J : NEXT I
30 PRINT D$;"PR#2"
40 FOR I = 1 TO 9: READ J : POKE 769,J : CALL 768 : NEXT I
50 PRINT D$;"PR#0"
60 DATA 169,4,76,237,253,96
65 REM ENTER COMMANDS IN LINE 70 AS ASCII CODES
66 REM BE SURE FOLLOW COMMAND STRING WITH A RETURN (ASCII 13)
70 DATA 65,84,83,48,61,50,53,53,13
```

Refer to the APM manual and the ASCII code chart for more information.

..TIL02030-PictureBaseTM_Application_Note_#1_(TA35905).pdf

The ID in a LMAP entry is the resource ID for the PICT, TILE, KYWD, and INFO for that page in the Library.

ID numbers are allocated randomly (as long as they don't already exist in that Library file).

IDs 0-128 are reserved for use by the system.

IDs 129-512 reserved for use by the PictureBase application.

PICT, TILE, KYWD, and INFO resources must be marked as purgable and not pre-loaded.

LaserWriter IINTX: Switch Configurations

Revised: 5/20/88
Security: Everyone

LaserWriter IINTX: Switch Configurations

=====

This article last reviewed: 15 January 1988

The LaserWriter IINTX has a bank of 6 DIP switches located on the controller panel. These switches are used for controlling the mode of operation, serial port configuration, and communication parameters. The switches will be preset to the AppleTalk configuration.

Switch 1	Switch 2	Meaning
Up	Up	8 pin AppleTalk (Serial Port Disabled)
Down	Up	25 pin RS-232 and 8 pin RS-422 * Serial Ports 1200 baud
Up	Down	25 pin RS-232 and 8 pin RS-422 * Serial Ports 9600 baud
Down	Down	25 pin RS-232 serial port 9600 baud;** 8 pin RS-422 serial port 0 baud

Switch 3	Switch 4	Meaning
Up	Up	PostScript Batch
Down	Up	Diablo 630
Down	Down	HP LaserJet
Up	Down	PostScript Interactive

Switch 5	Switch 6	Meaning
Down	Down	No Handshake

Up	Up	ON/XOFF
Down	Up	Etx/Ack
Up	Down	DSR

* Both serial ports are enabled. Serial communication and AppleTalk communication are NOT compatible, and will never occur at the same time.

** This configuration allows you to use the 25 pin RS-232 port while leaving LocalTalk connected. This prevents serial communication from interfering with the AppleTalk Network.

The switch configuration settings are maintained between power-off and power-on cycles by the 2K battery-backed-up ZPRAM (Zero-Power-RAM) equivalent to the EEROM of the LaserWriter IINT. The same PostScript commands that are used to modify the EEROM parameters will ALSO set or read the ZPRAM parameters. Consistency between the switch configurations and the ZPRAM is maintained through the VIA. Toggling a switch, waiting 30 seconds, then toggling the switch back forces the ZPRAM to update to the current switch settings.

LaserWriter IIscc: Controller Description

Revised: 4/8/94
Security: Everyone

LaserWriter IIscc: Controller Description

=====

This article last reviewed: 15 January 1988

LaserWriter IIscc is a personal laser printer that communicates through the SCSI port. The LaserWriter IIscc controller consists of:

- a Motorola MC68000 microprocessor (7.46MHz)
- 16K bytes of ROM
- 1 megabyte of RAM
- two 50-pin SCSI connectors
- a switch for setting the SCSI device number
- Apple Desktop Bus connector.

The printer ROM does NOT contain a page description language such as the PostScript language interpreter. All imaging is done in the Macintosh using QuickDraw and a set of specially designed four times (4x) fonts (such as 48, 56, 72, 96 point) which are stored in the Macintosh System File. QuickDraw commands are intercepted and translated by the LaserWriter IIscc driver, which draws each object into an offscreen bit-map in the Macintosh RAM.

The LaserWriter IIscc is configured with 1 megabyte of dynamic RAM, which is primarily used as a page-frame buffer for constructing the bit-mapped page image. They are 64-pin printer SIMMs, 120 nS access time, and interchangeable with the LaserWriter IIntx SIMMs.

Even though the hardware supports up to 4 megabytes of RAM, the software utilizes only 1 megabyte -- which is all that is required to represent a full page bitmap.

The host sends bit-mapped data and control commands to the LaserWriter IIscc controller over the SCSI bus; there is no support for the AppleTalk Personal

Network or serial communications.

	Printer with Controller	Controller Only
Marketing Number:	M6200	M6003

Controller Panel

ADB Port

The ADB port in the LaserWriter IIsC ROM supports printer enhancements -- i.e.: cut sheet feeders, bin feeders, output collators. The LaserWriter IIsC does NOT provide any power to the ADB bus. Refer to the ADB specifications for information about the ADB hardware and protocol currently available from Developer Support or Software Licensing.

SCSI Address Switch

This is the only switch on the controller panel. It is a pushwheel-type switch with a numeric display that indicates the address to the user. It will be preset to SCSI address "4".

CAUTION: The SCSI Address Switch should always be assigned a value in the range of 2 to 6; an internal SCSI hard disk is always ID "0" (zero) and the Macintosh is always ID "7". The SCSI ID number for the printer must be different from any SCSI hard disk in the SCSI chain. There is a remote possibility that data on a hard disk which is inadvertently assigned the same ID as the printer would be destroyed when attempting to print to the printer.

SCSI Port

There are two 50-pin SCSI connectors on the controller panel. Only ONE Macintosh may be connected to the printer at one time. The LaserWriter IIsC does supply terminator power to the connectors, but does not have an internal terminator.

Security: Everyone

AppleColor RGB Monitor: How To Connect It To The Apple IIfc

=====

This article last reviewed: 29 September 1988

While limited to only 8 colors, the AppleColor RGB Monitor does work with the Apple IIfc with:

1) a Telexmax Inc. "Peacock" RGB interface for the complete connection (like the connection for the Apple Color 100 Monitor)
and

2) a new interface cable, the pinouts of which are:

DB15 Pin	DB15 Pin
1 <----->	6
2 <----->	5
3 <----->	3
5 <----->	2
6 <----->	1
9 <----->	9
10 <----->	10
13 <----->	13
Shell <----->	Shell

LaserWriter IIntx: What The ROM/Font Expansion Card Is For

=====

This article last reviewed: 15 January 1988

The purpose of the LaserWriter IIntx Font Expansion Card is to provide additional ROM storage for fonts. The fonts must be stored either as character bitmaps or as character outlines. Refer to the PostScript Language Reference Manual for the character outline definitions and contact Adobe Systems for information about conforming to the Adobe cartridge-font definition.

The Font Expansion Card, 5.25 x 4.6 inches, interfaces with the controller ROM through a 96-pin DIN connector.

For more information about cartridge-font definition, search under: Adobe Systems Inc.

Apple IIc: Memory Expansion Card

Revised: 11/10/88
Security: Everyone

Apple IIc: Memory Expansion Card

=====

This article last reviewed: 10 November 1988

The Apple IIc Memory Expansion Card is a dealer-installed option available for Apple IIc computers that have a memory expansion connector. The card requires a memory expansion connector found on the IIc logic board. Simply exchange a logic board that does not have the connector for a board with the connector.

The Memory Expansion Card is sold with 256K RAM and may be expanded to 512K, 768K, or 1 Megabyte of RAM. Additional memory may be added at any time by plugging 256K RAM increments into the board's sockets.

Note that the Memory Expansion Card is static sensitive, so that proper electrostatic discharge precautions must be taken before handling the card.

The Memory Expansion Card will be available under ProDOS as a RAM disk, with the name /RAM4. Some software, such as AppleWorks 2.0, will use the extra RAM within the program.

To test the Memory Expansion Card, power on the Apple IIc and follow these steps:

1. Simultaneously press CTRL and RESET
2. Type CALL -151(CR)
3. Type C40AG(CR)

The Apple IIc responds with a message that indicates the RAM size found (256, 512, 768K, or 1M) and then tests the card until an error or until you press ESC.

The Memory Expansion Card test on an Apple IIc will give results whether or not a card is actually installed. You must make sure that a card is properly installed before getting valid results from the test.

When you run the diagnostics and there is no card, you should see:

MEMORY CARD TEST
ESC TO EXIT
TEST WILL TAKE 180 SECONDS
CARD SIZE = 1 MEG

PASSES = 0000

CARD FAILED
ADDRESS ERROR
SEE DEALER FOR SERVICE

8002- M=00 A=04 X=C1 Y=A0 P=B0 S=CE

(M is the memory bank where failure occurred)

If this is the message you are getting, then you may not have a RAM card
(or it may not have RAM in it).

There is no other way of determining how much memory the Apple IIC has
without writing a machine language program.

LaserWriter IINTX SCSI Hard Disks: General Information

Revised: 9/16/93
Security: Everyone

LaserWriter IINTX SCSI Hard Disks: General Information

=====

Article Created: 15 January 1988
Article Reviewed/Updated: 15 September 1993

Configuring the hardware:

The extended ROM support of a disk-based file system and the 53C80 SCSI controller with a 50-pin external connector allows you to attach one or more SCSI hard disks to the LaserWriter IINTX. The addition of a hard disk acts as "virtual memory", increasing the space available for font storage, font caching, or a display list buffer.

When connecting hard disks to the LaserWriter II, follow the standard SCSI procedures:

- each disk drive must have a unique SCSI ID number
- no more than two SCSI cable terminators in a chain
- no more than 7 devices.

The LaserWriter IINTX controller does NOT provide termination of the SCSI signals or active power for external terminators.

LaserWriter IINTX will NOT recognize any of the attached disks unless they are ALL turned on when you want to use any one of them.

(NOTE: some manufacturer's disk drives do not have the intelligence to report their size. These disk drives SHOULD NOT be used on the LaserWriter IINTX.)

Initialization:

Initialize the disks and download fonts to them with the LaserWriter Font Utility application on the LaserWriter II installation disk.

Initialization allots 20 percent of total disk space to font storage, and 80

percent to font-caching. The LaserWriter IINTX automatically increases the storage percentage as needed. The Font Utility application warns you when the percentage is high enough to threaten font-caching performance.

The LaserWriter IINTX regards all attached hard disks as a single logical unit. Therefore, if you add a disk to the system you will have to re-initialize ALL your disks and rebuild your font storage. The font cache rebuilds itself automatically. Because you can chain several hard disks, the space available for font-caching is essentially unlimited, and thus the bit-maps are always available.

Downloading:

When you download a font (and you have a hard disk attached,) you can choose to download it either to the disk or to RAM. Downloading fonts to the disk stores them there permanently (until you remove them). This process saves time, because you won't have to download repeatedly over the AppleTalk network.

Start-up Sequence:

Postscript checks the disk device for file-system integrity -- and the disk-based font cache for internal consistency -- each time the LaserWriter IINTX is turned on. If the check for file-system integrity fails, the disk device is re-initialized; for this reason you should ensure that ALL data on the device is recoverable from another source.

If the check of the internal consistency of the disk-based font cache fails, the information in the font cache is discarded, and associated data structures and files are restored to their initial state. If these start-up diagnostics are completed successfully, PostScript searches the disk device for a file named Sys/Start.

Sys/Start File:

A Sys/Start file can be used to set volatile parameters and to load special items into virtual memory before any other job is executed. If a Sys/Start file is stored on the disk device, it will be executed if "dosysstart" is true, right after completion of the start-up diagnostics.

If the file has become corrupt, it is necessary to restart the printer with the disk device turned off. To prevent the file from being run, you need to set "dosysstart" to FALSE -- then the Sys/Start file would not be executed the next time the printer is turned on. (To replace the bad Sys/Start file, restart the printer with the disk device turned on.)

Storing/Replacing the Start-up File:

The procedure used to download your Sys/Start file to the printer's disk device is broken into two PostScript programs to preserve virtual memory, which

is consumed when working outside the server loop:

(NOTE: Virtual memory is not recovered until the printer is powered-down and on again. To protect the system files, it is necessary to work outside the server loop when accessing these Sys files.)

- The first job stores the text of your Sys/Start file to a temporary file. It is not necessary to exit the server loop to perform this function.

- The second job exits the server loop, deletes the Sys/Start file if one already exists, and renames the temporary file to Sys/Start.

Actual code is provided in the current Apple LaserWriter Reference manual.

Apple IIGS: Alternate Display Mode Desk Accessory

Revised: 9/22/89
Security: Everyone

Apple IIGS: Alternate Display Mode Desk Accessory

=====

This article last reviewed: 16 September 1986

The Alternate Display Mode is a small firmware routine that can be activated from the Desk Accessory menu. It makes the Apple IIGS compatible with applications that display text or graphics on Page 2 (memory \$800-\$BFF).

The Apple IIGS does not shadow this range of memory to the Mega II normal RAM. However, some programs depend on this shadowing in order to display Text or Low-Res Graphics from Page 2. These programs will not work because the hardware is not updating the slow screen memory with the appropriate memory range from the Fast RAM.

Enabling the Alternate Display Mode will install a small routine into the Heartbeat Manager routine queue. This fast routine copies the appropriate values every 1/60 of a second, assuming that VBL interrupts have been turned on and the Heartbeat Manager has been initialized. While this slows overall execution speed of any programs on the Apple IIGS, they still run faster than on an Apple IIe or Apple IIc.

For more information on the Apple IIGS Heartbeat Manager, see the Apple IIGS Firmware Reference Manual or the appropriate database article.

Apple IIGS Super Control Panel: Refresh rate

Revised: 9/16/86
Security: Everyone

Apple IIGS Super Control Panel: Refresh rate

=====

From the Control Panel on the Apple IIGS, one can set many of the system configuration settings stored in the battery RAM. These include such settings as screen color, microprocessor speed, slot assignment, and others. However, one of the configurable settings that is not included as an option in the Control Panel is the screen refresh rate.

Because the Apple IIGS is an international machine, it must be able to conform to European standards. In Europe, the screen refresh rate is 50 Hz, rather than 60 Hz as defined by the U.S. standard.

In order to change the screen refresh rate, one must enter the "Super" Control Panel. This control panel is kept separate from the regular Control Panel for safety reasons. No harm will come to the Apple IIGS or the monitor if the refresh rate is incorrectly set. However, the screen display may become unreadable as long as the incorrect mode is set. The Super Control panel was made less accessible so that it would be more difficult to accidentally change the setting.

Entering the Super Control Panel is done by re-booting the computer in a special way. Rather than pressing Open-Apple/CTRL/Reset, the normal key sequence for rebooting, simultaneously press OPTION, CTRL, and Reset. The computer will cold start and then display the Super Control Panel screen. From there one can change the screen refresh rate, enter the regular Control Panel, or continue with the boot process.

Security: Everyone

Apple IIGS System Disk: Overview

=====

This article last reviewed: 16 September 1986

Every Apple IIGS user needs at least one complete system disk. This disk is shipped with every Apple IIGS system, and is provided on an 800K, double-sided, 3.5 inch disk; the complete set of files will not fit on a 5 1/4" disk.

CONTENTS OF A COMPLETE APPLE IIGS SYSTEM DISK

DIRECTORY/FILE	DESCRIPTION
PRODOS	A routine that loads the proper operating system and selects an application, both at boot time and whenever an application quits.
SYSTEM/	A sub-directory containing the following files:
P8	ProDOS/8 operating system kernel and loader
P16	ProDOS/16 operating system kernel
LOADER	The Apple IIGS System Loader
START	The Apple IIGS Finder
LIBS/	a sub-directory containing the standard system libraries
TOOLS/	a sub-directory containing all RAM-based tools
FONTS/	a sub-directory containing all fonts
DESK.ACCS/	a sub-directory containing all desk accessories
SYSTEM.SETUP/	a sub-directory containing system initialization programs
TOOL.SETUP	a load file containing patches to ROM and a program to install them. This is the only required file in the SYSTEM.SETUP sub-directory; it is executed before any others in the sub-directory
BASIC.SYSTEM	The Applesoft BASIC system interface program

These are all of the programs that come on a standard and complete System disk. In many cases, however, an application will not need all of these files, and some may be removed. The following is a list of the required files, and a short description of when it is safe to remove the others:

DIRECTORY/FILE	REQUIRED/(REQUIRED IF...)
-----	-----
PRODOS	required
SYSTEM/	required
P8	(required if the application is ProDOS/8-based)
P16	required
LOADER	required
START	(required if the application works from the Finder)
LIBS/	(required if the application uses the standard libraries)
TOOLS/	(required if the application needs RAM-based tools)
FONTS/	(required if the application needs fonts)
DESK.ACCS/	(required if the application supports desk accessories)
SYSTEM.SETUP/	required
TOOL.SETUP	(required if the application uses ROM-based tools)
BASIC.SYSTEM	(required if the application is written in Applesoft)

SYSTEM STARTUP

Disk blocks 0 and 1 on an Apple IIGS system disk contain the startup (boot) code. They are identical to the boot blocks on Apple IIe/IIc system disks. This allows ProDOS system disks to boot on an Apple IIGS, and it also means that the initial part of the ProDOS/16 bootstrap procedure is identical to the procedure for ProDOS. For a system disk with a volume name of /SYS, the boot process is outlined as follows:

1. The boot code searches the disk's volume directory for the first file named /SYS/PRODOS with the file type \$FF.
2. If the file is found, it is loaded and executed at location \$2000 of bank \$00. If it is not found, then a message stating that PRODOS cannot be found on the disk is displayed.

On an Apple IIe/IIc system disk, the file named PRODOS is the ProDOS operating system. On an Apple IIGS system disk, however, this PRODOS file is not the operating system itself; it is an operating system loader and application selector. When it receives control from the boot code, /SYS/PRODOS on the Apple IIGS performs the following tasks:

3. It relocates the part of itself name PQUIT to an area in memory where PQUIT will reside permanently. PQUIT contains the code required to terminate one program and start another.
4. /SYS/PRODOS loads the ProDOS/16 operating system kernel.
5. Using ProDOS/16 calls, /SYS/PRODOS loads the System Loader.
6. /SYS/PRODOS performs any necessary boot initialization of the system by executing the files in the sub-directory /SYS/SYSTEM/SYSTEM.SETUP. If there is a file named TOOL.SETUP in that sub-directory, it is executed first -- it loads RAM-based tools and RAM patches to ROM-based tools.

Every file in the sub-directory /SYS/SYSTEM/SYSTEM.SETUP must be an Apple IIGS load file of type \$B6. /SYS/PRODOS loads it and makes a JSL to each file in turn; when the file returns with an RTL, /SYS/PRODOS unloads it from memory.

7. Now /SYS/PRODOS selects which program to run.

- a. It first searches for a type \$B3 file named /SYS/SYSTEM/START. Typically, that file is the Apple IIGS Finder, but it could be any Apple IIGS system program. If START is found, it is selected.
- b. If there is no START file, /SYS/PRODOS searches the boot volume directory for the first file that is either (1) a ProDOS system program (type \$FF with the filename extension .SYSTEM), or (2) a ProDOS/16 system program (type \$B3 with the filename extension .SYS16). Whichever is found first is selected.

Note: If a type \$FF file is found first, but the ProDOS operating system (file /SYS/SYSTEM/P8) is not on the system disk, /SYS/PRODOS will then search for and select the first ProDOS/16 system program.

- c. If /SYS/PRODOS cannot find a file to execute, it will bring up an interactive routine that prompts the user for the filename of a system program to load.

8. Finally, /SYS/PRODOS passes control to an entry point in PQUIT. It is PQUIT, not /SYS/PRODOS, that actually loads and executes the selected program.

Apple IIGS Incompatibilities: Communications software

=====

The Apple IIGS is designed to be used with the vast majority of Apple IIe hardware and software. However, there are some design differences that will cause some products to be incompatible with the Apple IIGS.

A number of communications packages written for the Apple IIe bypassed the firmware available for the system. Those software programs that write directly to the IIe hardware cannot be used on the Apple IIGS, since the serial ports are now controlled by a 8530 Serial Communications Chip, rather than a 6551. Most currently available communications packages, including Access II, version 1.1, do not work on an Apple IIGS.

Apple IIGS Incompatibilities: Slot 2 and ProDOS 1.2

=====

This article last reviewed: 17 September 1986

The Apple IIGS is designed to be used with the vast majority of Apple IIe hardware and software. However, there are some design differences that will cause some products to be incompatible with the Apple IIGS.

When a RAM disk or ROM disk is used with ProDOS 8 and at least two disk drives are connected to the SmartPort, the IIGS maps the second (and third) drives into slot 2. This function will conflict with those multi-function cards manufactured for the Apple IIe which normally reside in slot 2. Since phantom slots are used by both the multi-function card and ProDOS 1.2, the two cannot be used in the same machine.

Apple IIGS: How To Disable Keyboard Repeat

=====

This article last reviewed: 8 January 1988

People with limited motor skills sometimes can't adapt to the keyboard repeat rate on the Apple IIGS, causing several characters appear after each keypress.

The keyboard repeat rate can be set from the Control Panel. Here's how to disable keyboard repeat altogether:

1. In the Control Panel, select the Options menu.

The 'repeat delay' option controls the time between the first keypress and the time when keys begin auto repeating.

2. To disable the auto repeat feature, move the asterisk all the way to the left of the sliding scale.

3. To save the changes made to the Control Panel, press Return.

Apple IIGS: Connecting Disk Drives

Revised: 10/12/87
Security: Everyone

Apple IIGS: Connecting Disk Drives

=====

This article last reviewed: 22 September 1986

The Apple IIGS is capable of using all drives available for the Apple IIe, as well as drives built for the Apple IIGS, including the Disk II, Duodisk, Unidisk, Unidisk 3.5, Profile, Apple 3.5 Drive, Apple 5.25 Drive, and SCSI-20. Some of these drives may be plugged directly into the SmartPort on the back of the IIGS, while others require an interface card in one of the expansion I/O slots.

The following drives may be plugged into the SmartPort's DB-19 connector:

- one Duodisk
- two Unidisk 5.25 drives
- two Unidisk 3.5 drives
- two Apple 5.25 drives
- two Apple 3.5 drives

Only under Prodos 16 may a combination of up to six drives be daisy-chained to the SmartPort. The chain MUST occur in the order given below and may include up to two (excepting the DuoDisk) in each of the following three categories:

- nearest to IIGS (maximum of two):
 1. Apple 3.5 Drives
 2. Unidisk 3.5 drives
- farthest from IIGS (maximum of two):
 3. 5.25 disk drives: Disk II's, Unidisk 5.25 drives, Apple 5.25 drives or ONE Duodisk drive

Under Prodos 8 (also known as Prodos 1.2), four drives are accessible through the SmartPort. These may be a combination of Apple 3.5 drives, Unidisk 3.5 drives, a RAM disk, and a ROM disk, under the same order restrictions as above.

The SmartPort is mapped to slot 5, so drives connected directly to the port are accessed as slot 5, drive 1 and slot 5, drive 2. When more than two drives are used under Prodos 8, or if the RAM disk is active, "phantom slots" are

assigned.

To be used on the Apple IIGS, the Disk II requires a Disk II Controller Card, just as on the Apple II or Apple IIe. The drive may be accessed through the slot used for the card, most likely slot 6, in which case the two possible drives are referred to as slot 6, drive 1 and slot 6, drive 2.

A SCSI Interface Card is needed to use the Apple Hard Disk 20SC on the Apple IIGS. A Profile Interface Card must be used with a 5 or 10 Megabyte Profile, accessible by referencing the slot where the interface card resides or by the ProFile's ProDOS pathname.

The Apple IIGS control panel allows you to select the slot from which the computer will be booted, or you may choose to scan slots on bootup to find a device that is ready.

This article last reviewed: 22 September 1986

The Apple IIGS is designed to be used with the vast majority of Apple IIe hardware and software. However, there are some design differences that will cause some products to be incompatible with the Apple IIGS.

Some Apple ProFile Interface Cards work incorrectly in an Apple IIGS and cause the information on the ProFile to be inaccessible. To avoid problems when using a ProFile in an Apple IIGS, either modify the interface card or obtain the new version of the card.

The Apple IIGS bus' higher 'noise' levels create the problem. The 'noise' is passed on to the ground traces on the ProFile interface card and will eventually (after use) corrupt the directory of the ProFile, rendering it invisible to ProDos and inaccessible to the user.

Apple IIGS: Recovering a corrupted ProFile

=====

This article last reviewed: 29 March 1988

In the Apple IIGS, the bus' higher 'noise' passes on to the ground traces on the ProFile interface card and, after use, corrupts the directory of the ProFile, rendering it invisible to ProDos and inaccessible to the user.

It is possible to recover the directory and make the ProFile usable again. On the report of a ProFile going bad after installation in a Apple IIGS, first see the article "Apple II ProFile Interface Card Modification for the Apple IIGS. This modification lets the card operate correctly for the directory fix. Don't try to repair a directory with an un-modified ProFile card.

For the recovery, use a disk editor program, like the ProDos MLI Exerciser program here:

1. Execute the ProDos Machine Language Interface Exerciser program with the '-' command and wait for the main menu.
2. From the main menu, type '80'<Return> to command a read of a block; follow that by typing in the following values from the next screen:

Parameter Count	\$03 (Default)
Unit Number	\$50 (The ProFile card's slot followed by a '0')
Data Buffer	\$00 (This value is where the block to be modified \$40 will be loaded)
Block Number	\$02 (This is the bad block to load in) \$00

After typing in each pair of numbers, press <Return> to go on to the next entry prompt. After pressing <Return> on the last entry, you see a message 'PRESS RETURN TO EXECUTE COMMAND', you press <Return> and then see another message 'Error \$00: Call Successful'. At this point, press <Return> to get the main menu.

3. Type 'M' <Return> to modify the buffer. The default should read:

\$00
\$40

This is the correct setting; press <Return> on each entry and press it once more to go on to modify mode. At this point, you should see a table of numbers and a blinking cursor on the entry we want to 'delete', number '55'. Now that we know that problems with the directory exist, press <ESC> to go to the main menu.

If the '55' was not in the first position of the table, then this directory recovery procedure won't work. If the '55' was not shown at all, your ProFile possibly has a different reason for not operating)

4. Type '81' <Return> to write the block out to the disk. Press <Return> through the number entries until you reach the 'data buffer' entry. Change it to look like this:

\$01
\$40

Continue to press <Return> through the block number entries and once more to command the actual block write, after which you will see the message 'Error \$00: Call Successful' will be displayed.

5. You may now reboot your system and check to see if the ProFile is now recognized. All of the data previously inaccessible should be back and usable.

For more information about using the ProDOS Exerciser Program, see the ProDOS Technical Reference manual.

Apple IIGS: Cabling Configurations

=====

This article last reviewed: 22 September 1986

The Apple IIGS is very compatible with Apple's existing cable product line. Below you will find the possible configurations for the various Circular 8 cables.

Apple System Peripheral - 8 Cable
Product M0187 / Part 590-0340-A
Circular 8 to Circular 8

Can be used as connecting cable for the Apple IIGS to:

- ImageWriter //
- Apple Personal Modem
- Macintosh Plus (data transfe)
- Apple IIGS (data transfer)

Macintosh Peripheral - 8 Cable
Product M0185 / Part 590-0322-B
Circular 8 to DB9

Can be used as connecting cable for the Apple IIGS to:

- Macintosh 128K and 512K (data transfer)

In ny other required combination, use the Apple IIGS Adapter Cable (Circular 8 to DB25 adapter) and the appropriate DB-25 Apple II type cable used on the Super Serial Card.

Revised: 10/12/87
Security: Everyone

Apple IIGS: Composite Video Jack

=====

This article last reviewed: 24 September 1987

The Apple IIGS composite video output, a standard 'RCA' connector used for composite NTSC compatible monitors, does not always display in color. Because of effects known as color fringing (showing bits of color on the edges of white characters), the color burst signal is turned off when the computer is in text mode, making colored text, background, and borders appear as black, white, or shades of grey. Turning off the color burst eliminates color fringing and improves the legibility of text displayed on composite color monitors. However, it makes testing of the color modes of the Apple IIGS on a composite monitor impossible from a text-only program such as the Control Panel or the Apple IIGS Diagnostics.

Color burst is enabled whenever any of the graphics modes (lo-res, hi-res, or super hi-res) is switched on. Don't confuse the hi-res or super hi-res mode with the text mode: when characters are drawn on the graphics screen (as in the Apple IIGS Program Launcher, or when ProDOS 16 displays the 'One moment please...' message while starting up), users may get the impression that they are seeing text with a colored screen border, when in fact they're not.

Apple IIGS Connectors: Desktop Bus (9/95)

Revised: 9/21/95
Security: Everyone

Apple IIGS Connectors: Desktop Bus (9/95)

=====

Article Created: 22 September 1986
Article Reviewed/Updated: 21 September 1995

TOPIC -----

This article describes the Desktop Bus on the Apple IIgs computer.

DISCUSSION -----

The Apple Front Desktop Bus connector is an intelligent interface capable of handling many input devices, hand controllers, graphics tablets, numeric pads, although it is currently used for the keyboard and mouse attachments. A serial interface (not a standard serial port), the Desktop Bus is controlled by its own built-in microprocessor, the 'ADB microcontroller'. Desktop Bus devices use inexpensive four-conductor cables and four-pin miniature DIN connectors. Additional devices can chain to devices already installed. Some devices already include a jack for connecting additional devices.

Apple IIGS Connectors: Drive Port

Revised: 9/22/86
Security: Everyone

Apple IIGS Connectors: Drive Port

=====

A DB-19 female connector, the drive port on the back of the Apple IIGS is commonly referred to as the 'SmartPort'. Actually 'SmartPort' is a set of assembly language routines used to support block I/O devices. The 'SmartPort' firmware includes the Protocol Converter software used in the Apple IIc 3.5 ROM revision. Up to six drives (DuoDisk, Uni-Disk, Uni-Disk 3.5, Apple 5.25 Drive, Apple 3.5 Drive are all plug compatible with port) may be attached to the port at any one time.

Apple IIGS Connectors: Game I/O

Revised: 9/22/86
Security: Everyone

Apple IIGS Connectors: Game I/O

=====

The Game I/O setup on the Apple IIGS is exactly the same as the Apple IIe: the DB9 connector on the back of the machine and the 16 pin DIP socket on the main mother board. The DB9 connector has four analog inputs, three button inputs, power, and ground. The 16 pin DIP connector is the same but has a strobe line and four single-bit outputs. For pinouts, see the IIe Technical Reference Manual.

Apple IIGS Connectors: Serial Port Pinouts and Description

Revised: 9/22/86
Security: Everyone

Apple IIGS Connectors: Serial Port Pinouts and Description

=====

The serial port pinouts are as follows:
(Circular 8 Female on system end)

- 1 - HSKo
- 2 - HSKi
- 3 - TxD-
- 4 - Signal GND
- 5 - RxD-
- 6 - TxD+
- 7 - GPi
- 8 - RxD+

The Apple IIGS has two serial ports that can substitute for slots 1 and 2. You can choose to use either internal slot 1 or 2 or external port 1 or 2 through the control panel. The built-in port can operate while there is a peripheral card plugged into the corresponding slot, but the port and the card cannot operate at the same time.

The communication hardware are 2 channel SCC (Zilog 8530) and RS-422 driver IC's. The ports emulate the Super Serial Card firmware. Normally the ports are configured so that port 1 is the printer port and port 2 is the modem port. Via the control panel, you can turn one of the two ports into the AppleTalk connection.

Even though the same commands are used in the Apple IIGS serial port firmware as the Super Serial Card firmware, some existing programs using these ports will not be compatible because some of the programs (usually communication programs) bypass the firmware commands and access the hardware directly. The new communications chip in the Apple IIGS doesn't work with the programs that are hard coded for the 6551 chip on the SSC.

PC 5.25" Drive & Macintosh II PC Drive Card: Pinouts and Cabling

Article Created: 22 January 1988
Article Last Reviewed: 16 June 1992
Article Last Updated:

TOPIC -----

What are the pinouts for the Macintosh II PC Drive Card and PC 5.25" Drive?

DISCUSSION -----

Here is the pinout for the DB37 connector on the Macintosh II PC Drive card. Note that pins not listed are not used.

DB37	Signal Name
1 -----	+12 Volts
2 -----	Ground
4 -----	+ 5 Volts
5 -----	Ground
6 -----	INDEX
7 -----	Motor Enable
8 -----	Drive Select 1
9 -----	Motor enable
11 -----	Direction
12 -----	STEP
13 -----	Write Data
14 -----	Write Enable
15 -----	Track 00
16 -----	Write Protect
17 -----	Read Data
18 -----	Side 1
19 -----	Diskette Change
20 -----	Ground
25 -----	Ground

This is the pinout for the cable, part number 590-0368, used on the PC 5.25 inch drive. The cable uses a 34 pin connector and smaller 4 pin connector for the DC power on the inside of the PC 5.25 inch drive and a DB37 connector that attaches to the card in Macintosh II. Note that pins not listed are not used.

DB37	Signal Name	34 pin edge connector	DC Connector
1	+12 Volts		1
2	Ground		2
3	Low Density	2	
4	+5 Volts		4
5	Ground		3
6	Index	8	
7	Motor Enable A	16	
9	Drive Select A	10	
11	Direction	18	
12	Step	20	
13	Write Data	22	
14	Write Enable	24	
15	Track 00	26	
16	Write Protect	28	
17	Read Data	30	
18	Side 1	32	
19	Disk Change	34

Apple IIGS: Resetting And Buffer Clearing

Revised: 9/22/86
Security: Everyone

Apple IIGS: Resetting And Buffer Clearing

=====

Some Apple IIGS's will not reset when 'hung'.

The Apple IIGS has two levels of user reset: warm and cold. For a warm reset, hold down the 'Control' key and press and release the 'Reset' key. A 'cold' reset, which is a machine restart, requires you to hold down the 'Control' and 'Apple' keys and press and release the 'Reset' key, which makes the machine reboot as if it were just turned on.

The computer can't possibly recognize these resets usually when an application has bombed and hung the machine. The reset acts like any other keystroke in this case; moreover, if you already have some of the other keys pressed and waiting in the keyboard micro, the reset must wait its turn.

Remedy this problem with clearing the keyboard buffer by holding down the keys control and Apple and then pressing the backspace key. You can then press the reset sequence you want and the Apple IIGS can recognize it.

Apple II VisiCalc: How To Convert Its Files To MS-DOS

=====

This article last reviewed: 19 January 1988

Here's how to transfer Apple II VisiCalc files to an MS-DOS format:

1. Save the Apple II VisiCalc file to disk in the DIF format.
2. Transfer the file, via terminal software, to the MS-DOS system.
3. Save the file.

The file can now be read into any of the MS-DOS spreadsheet applications that support a DIF format -- Lotus 1-2-3, for example.

Pascal 1.3: Using UNITSTATUS

Revised: 9/22/86
Security: Everyone

Pascal 1.3: Using UNITSTATUS

=====

The Pascal 1.3 operating system on all Apple systems does not detect characters with the device REMIN:. For example, when an Apple IIc with the 3.5" ROM runs the sample program from volume III, page 191 of the Apple II Pascal 1.3 Workbench Manual, the characters from the modem port (i.e. REMIN:) are not detected.

In previous versions of Pascal, the programmer was requested to use the Applestuff function RemStatus instead of UNITSTATUS when he wanted to use REMIN: and REMOUT:. RemStatus was not included with Pascal 1.3.

To employ REMIN: and REMOUT: with Pascal 1.3, use the Library program to replace the 1.3 APPLESTUFF with the 1.2 APPLESTUFF, following the procedure on pages 216-222 of chapter 8 of the Pascal 1.3 manual, volume II.

After that procedure, the following function and types will be available:

```
TYPE RStatus = (RStatBusy, RStatReady, RStatOffline);  
      RSChannel = (RSOutput, RSInput);
```

```
FUNCTION RemStatus (channel: RSChannel):RstatType;
```

Use this function instead of UNITSTATUS.

Macintosh Power Sweep Voltage Adjustment

Revised: 7/17/92
Security: Everyone

Macintosh Power Sweep Voltage Adjustment

=====

Article Created: 8 October 1986
Article Last Reviewed: 17 July 1992
Article Last Updated: 17 July 1992

PROBLEM DESCRIPTION: Macintosh Plus, 512Ke, 512K has no video output or clicking sound is emitted from the power supply.

CAUSE: The voltage on the Power/Sweep board might need adjustment.

CURE: Use the following procedure in order to adjust the voltage inside the Macintosh:

POWER/SWEEP ADJUSTMENT

The voltages must be verified whenever the logic board or the power/sweep board is exchanged. If the voltages are outside of the specified tolerances, the adjustments must be performed.

The adjustments are done with the power on, and all voltage measurements are taken on the disk drive port with no peripheral device attached. The internal disk drive should not be running when the measurements are being taken.

EQUIPMENT REQUIRED: Digital Voltmeter (accurate to 0.1 volts)
Macintosh voltage test cable
Plastic alignment tool

NOTE: If you don't have the test cable, you may use wire that has been stripped of insulation at both ends. Insert one wire into one of the drive port pin locations indicated for ground (Pin 1 or Pin 2 of the DB 19). Connect the other end of this wire to the ground probe of the voltmeter. Insert the other wire into

the drive port pin location indicated for 5 or 12 volts (pin 6 for 5 volts or pin 7 for 12 volts). ALWAYS DOUBLE-CHECK THAT YOU ARE READING THE VOLTAGES FROM THE CORRECT PINS.

CAUTION: If the banana plugs on the test cable short one another, the Macintosh will be damaged. Make sure that the banana plugs are insulated by their rubber hoods when not in use.

1. The power should be off, and the back cover removed. Connect the black test lead to the ground, set the proper range on the the voltmeter and plug the connector into the disk drive port on the rear of the Macintosh.

2. Connect the orange test lead (12 volts) to the input on the voltmeter. Power on the Macintosh.

The voltage reading must be between 11.90 and 12.75 volts. If the voltage is not within these tolerances, use the alignment tool to adjust the voltage regulator on the power/sweep board to 11.90 to 12.75 volts. Access to voltage regulator is gained from the noncomponent side of the power/sweep board through the hole just above the 11 o'clock position of the speaker.

3. Power off the Macintosh. Disconnect the orange test lead and replace its insulating hood.

4. Connect the red test lead (5 volts) to the input on the voltmeter. Power on the Macintosh.

The voltage reading must be between 4.85 and 5.15 volts. If the voltage is not within these tolerances, use the alignment tool to adjust the voltage regulator (see step 2 for location of the voltage regulator access hole) on the power/sweep board to the specified limits.

6. Power off the Macintosh. Disconnect the red test lead and replace its insulating hood.

7. Return and repeat steps 2 through 6 to verify that both voltages are within the specified tolerance ranges.

IMPORTANT: If the power/sweep board cannot be adjusted so that BOTH voltages fall within the tolerances indicated above, it should be exchanged.

Apple IIGS: Differences with other Apple II models

=====

Some of the features found only on the Apple IIGS:

FEATURE -----	SPECIFICATION -----	DESCRIPTION -----
More powerful microprocessor	65C816	16-bit microprocessor has 24 bit address and 6502 compatibility
Faster Operation	CPU clock speeds of 1 MHz and 2.8 MHz	User can select either of two speeds: 1 MHz speed of 6502 or fast 2.8 MHz.
Memory Expansion	24-bit address bus	Expansion card can expand RAM up to as much as 8 megabytes
Detached Keyboard	78 keys	Separate keyboard includes cursor keys and numeric pad.
Apple DeskTop Bus	Low cost serial I/O	Supports detached keyboard, mouse, and other I/O devices.
RGB Video	R, G, B and sync	Provides both RGB and NTSC video outputs.
40 and 80 column text in color	Text, background, and border colors (RGB only)	Text, background, and border can be any of sixteen colors.
Super Hi-Res color	True 320x200 or 640x200	Improved graphics with up to 16 graphics colors per scan line-up to 256 colors on screen out of 4096.
Desktop user interface	Uses Hi-Res color graphics and mouse	Tool box supports desktop interface with mouse, menus, and windows

Improved Sound	Ensoniq digital sound IC with 32 oscillators	Supports 15 independent voices (GS retains Apple II type sound)
Control Panel	Built-in desk accessory	User may set machine parameters for display, operating speed, serial ports, disk drives, etc.
Enhanced Monitor	Monitor in ROM	Handles 16-bit and 24-bit addresses, assembles and disassembles 65C816 and 6502 instructions, performs 32-bit arithmetic, Low level I/O included
Built-in Clock	Time and Date provided	Has battery back up
Built-in Serial ports	Two standard serial ports	Support modems, printers, and AppleTalk. (User can still use serial card in slot)
Built-in AppleTalk	Uses one serial port	No card required. User can select either serial port to use for AppleTalk.
Built-in Disk port	Disk I/O port using custom chip	User can select built-in driveport, disk interface cards, or both.

Apple II type features found on the Apple IIGS:

FEATURE	DESCRIPTION	OTHER MODELS
-----	-----	-----
6502 Instruction set	65816 has emulation mode for running 6502 programs	All Apple II
128k RAM	Main and aux banks, with language-card & I/O spaces	IIc, 128 IIe
AppleSoft in ROM	Applesoft Basic with lower case and 80-column features	All Apple II
Monitor in ROM	Supports low level I/O and program development	All Apple II
40 and 80 column text	Black & White text displays (color text on GS only)	IIc, IIe with 128k or 80 column card
Lo-Res Color graphics	48x40, 16 colors	All Apple II

Hi-Res Color graphics	280x192, 6 colors	All Apple II
Double Hi-Res Color graphics	560x192, 16 colors	IIc, 128k IIe
Built-in serial ports	Two RS232 compatible ports, IIc (similar) for modem, printer, etc.	
Built-in disk port	Using IWM chip, supports both 5.25", 3.5" drives	IIc
Expansion slots (7)	Slots for peripheral I/O and expansion cards, in addition to built-in ports	II, II Plus, IIe
Game I/O	9-pin and 16-pin connectors for paddles and joysticks	All Apple II (9 pin IIe, IIc)

TOPIC -----

The following table identifies compatible peripherals for the Apple II line of computers.

DISCUSSION -----

The X means that the peripheral product is compatible with the CPU. The footnotes explain the numbers.

Item	Apple II CPU				
	II Plus	IIe	IIc	IIc(new)	IIGS
Drives					
Disk II	X 1	X 1	9	9	X 1
DuoDisk	X 2	X 2	14	14	X
Unidisk	X 2	X 2	X	X	X
Unidisk 3.5	X 3,7	X 3,5		X	X
IIc External	X 2	X 2	X	X	X
Apple 3.5					X
Apple 5.25	X 11	X 11	X	X	X
Profile (5M,10M)	X 4,7	X 4			X 4
Hard Disk 20SC	X 6,7	X 6			X 6
Cards					
II Memory Expansion	X 7	X			X
IIc Memory Expansion				X	
IIGS Memory Expansion					X

Super Serial	X	X	8	8	X
Parallel Interface	X	X	9	9	X
80-column		X	8	8	
Extended 80-column		X	8	8	
Apple Modem 300/1200	X 12	X 12	X	X	X
Apple Personal Modem	X 12	X 12	X	X	X
Imagewriter	X 12	X 12	X	X	X
Imagewriter II	X 12	X 12	X	X	X
Daisy Wheel Printer	X 12	X 12	X	X	X
LaserWriter	X 12	X 12	X	X	X
Monitors					
II	X	X	X	X	X
IIc	X	X	X	X	X
ColorMonitor IIc, IIe	X	X	X	X	X
ColorMonitor 100		X 10	9	9	
AppleColor RGB	9	9	9,13	9,13	X
AppleColor Composite	X	X	X	X	X
Monochrome	X	X	X	X	X

Footnotes:

- 1 - Requires Disk II controller card
- 2 - Requires Duodisk/Unidisk controller card
- 3 - Requires Unidisk 3.5 controller card
- 4 - Requires Profile Interface Card
- 5 - Will auto boot on an enhanced IIe
- 6 - Requires Apple II SCSI Card
- 7 - Requires 64K RAM for ProDOS
- 8 - This function is built into the Apple IIc
- 9 - A third party solution is available
- 10- Requires Extended 80-Column AppleColor Card
- 11- May be daisy-chained from a Unidisk
- 12- Requires a Super Serial Card
- 13- Limited color capability
- 14- Will only have access to one of the drives

Note: "IIe" stands for either the unenhanced or the enhanced Apple IIe.
 "IIc(new)" refers to an Apple IIc with memory expansion socket.

Apple IIGS: Sound Logic

=====

This article last reviewed: 23 October 1986

To support sound, the Apple IIGS has the Apple IIGS Sound General Logic Unit, an Ensoniq sound chip, 64K of dedicated sound RAM, and associated circuitry.

Sound General Logic Unit

The Apple IIGS Sound General Logic Unit (Sound GLU) provides an interface between the Ensoniq sound chip and the remainder of the Apple IIGS logic system. The Sound GLU permits the Ensoniq chip to run independently of the Mega II chip.

The Sound GLU contains a control register, data register, and address pointer. Bits within the control register determine the system volume level and control the flow of information between the Ensoniq chip and Sound RAM. The data register and address pointer are used to transfer information to and from the dedicated 64K of Sound RAM to the Ensoniq digital oscillator chip.

Ensoniq Digital Oscillator Chip

The Ensoniq chip contains 32 oscillators, two of which are reserved for use by the Apple IIGS itself. The remaining 30 oscillators are used in pairs to produce 15 sound voices. Each oscillator uses seven DOC registers which contain such parameters as the frequency rate at which the oscillator steps through its wavetable, the size and starting address of the wavetable, data obtained from the wavetable, and the volume and mode of the oscillator.

Sound RAM

64K of RAM is provided for the exclusive use of the Ensoniq DOC. It contains wavetables, which are digitized waveforms, for each of the oscillators.

LaserWriter Generates Documents with Missing Portions of Print

Revised: 1/17/92
Security: Everyone

LaserWriter Generates Documents with Missing Portions of Print

=====

This article last reviewed: 29 March 1988

BEFORE YOU START: Familiarize yourself with the LaserWriter Technical Procedures. Be sure to follow proper ESD procedures.

PROBLEM DESCRIPTION: The LaserWriter printer generates documents with missing top and side portions. The LaserWriter test print is missing the vertical lines that make up its outer border.

#1 - CAUSE: The paper cassette might be deformed, causing the printer to assume that larger size paper is being used.

CURE: Swap the paper cassette and generate a test print.

#2 - CAUSE: A legal-size paper tray is possibly being used.

CURE: Install a standard-size paper tray if legal-size paper is not what the user intended for the print job.

#3 - CAUSE: The paper cassette detect switch assembly is bent or damaged. This can be caused by rough handling of the paper tray during insertion or removal of the paper tray.

CURE: Replace the paper cassette detect switch assembly in the LaserWriter pedestal. Be sure to refer to the LaserWriter Technical Procedures for instructions on removing the printer from the pedestal.

Macintosh Displays Single Raster Line

=====

Article Created: 28 October 1986
Article Last Reviewed: 17 July 1992
Article Last Updated:

PROBLEM DESCRIPTION: The Macintosh displays a single white raster line. The line is usually positioned horizontally or vertically across the screen.

BEFORE YOU START: Familiarize yourself with Macintosh Technical Procedures. ALWAYS DISCHARGE THE CRT TO THE "GROUND LUG". The Macintosh uses an isolated ground. Performing a discharge to the chassis will DESTROY the logic board!

CAUSE: In most cases this is an indication of a faulty Power Supply Board but there exists a possibility that more than one module is defective.

CURE: Replace the modules in the following order:

1. Replace the power supply and test. If the system is still inoperative perform Step 2.
2. Replace the Logic Board. If the system is still inoperative perform Step 3.
3. Replace the CRT. If the system is still inoperative perform Step 4.
4. Replace the Power Supply and the Logic board as a set.

ProFile Formatting Error #21

Revised: 1/17/92
Security: Everyone

ProFile Formatting Error #21

=====

This article last reviewed: 29 March 1988

PROBLEM DESCRIPTION: Error #21 is generated when the ProFile is formatted using the Apple III System Utilities.

BEFORE YOU START: Familiarize yourself with the Apple III Owners Guide and ProFile Owners Manual.

CAUSE: Software damage has occurred.

CURE: Use the following procedure:

1. Format the ProFile using the Apple III Systems Utilities and define the volume name as HVRMHGL. Another volume name can be defined once the ProFile has been formatted.

Proceed to Step 2 if you again receive the error #21.

2. Format the ProFile using an Apple II/IIfx with the ProDos utilities. Reconnect the ProFile to the Apple III once the ProFile has been successfully formatted and perform Step 1.

Use the ProFile troubleshooting procedure (documented in ProFile Technical Procedures) if both Steps 1 and 2 fail to produce satisfactory results.

Apple IIGS: Video Generation Chip (VGC)

Revised: 10/12/87
Security: Everyone

Apple IIGS: Video Generation Chip (VGC)

=====

This article last reviewed: 23 October 1986

The Video Generation Chip (VGC) supports video output from the Mega II for both Apple II graphics and Super Hi-res graphics, provides an interface to the Real Time Clock chip, supports interrupt handling, and assists disk drive interfacing.

The VGC accepts color information from the Mega II, modifies it according to the current Control Panel selections, and puts out appropriate display information for the NTSC composite video jack and the Video RGB port. The VGC accesses text, background, and border information maintained in the Text and Background Color Register and Border Color Register. 4-bit value determines each of the three color areas, so that there are 16 possible colors for each. These colors correspond to the 16 Apple II Lo-res colors.

Apple II Graphics and Text

If Apple II text mode is used, the VGC removes color information from the NTSC composite output signal, so that color fringing does not occur on a color composite monitor. If a mixed text/graphics mode is chosen, color fringing is unavoidable, since most composite monitors do not have the ability to respond quickly enough to a change in the chroma information. In this case, the bottom four lines of text will show a color fringing anomaly.

The VGC polls the Monochrome/Color Register to determine which type of video signal should be output. If monochrome has been chosen, the VGC will output appropriate dot patterns to represent the chosen colors, so that a monochrome composite monitor will display gray-scale images. An AppleColor RGB Monitor displaying double Hi-res graphics will also display gray-scale images if monochrome is selected.

Super Hi-res Graphics

After the selection of one of the new Apple IIGS Graphics modes, the VGC is responsible for implementing the color mode. It uses memory in the auxiliary

64K bank of Apple II RAM to implement Super Hi-res graphics. In this display buffer, locations \$2000-\$9CFF are used for pixel information, \$9D00-\$9DFF are pointers that determine the characteristics of each line, and \$9E00-\$9FFF hold color palette information.

For 640 or 320 graphics modes, each pixel may be represented respectively by either 2 or 4 bits, wherein the value is a number of a color in the appropriate color palette. Each of the 200 pointers (one for each line) stores the display mode used, the color palette associated with that line, and a flag of enabled or disabled for scan line interrupts. Each of the 16 color palettes contains information on 16 colors. Each of the colors takes two bytes: 4 bits each for the value of red, green, and blue, which allows the three primary colors can be combined in 4096 different ways.

Real Time Clock Interface

The Video Generation Chip also works as an interface between the 65816 microprocessor and the Real Time Clock Chip (RTC). A Real Time Clock register in the VGC is used as a command register for the RTC. The RTC then maintains calendar and clock information within parameter RAM.

VGC Interrupts

Two types of internal interrupts are handled by the VGC: the One-Second interrupt generated by the Real Time Clock Chip and the Scan-Line interrupt generated by scan line information in Super Hi-res mode. The status and enable states of these interrupts are found in the VGC Interrupt Register and the VGC Interrupt Clear Register. The VGC also handles one external interrupt line.

VGC Disk Register

The VGC Disk Register, used as a control register for the disk drive interface, functions in choosing the head to use and the type of drive selected.

Apple II SCSI Card: Product Description (11/96)

Revised: 11/21/96
Security: Everyone

Apple II SCSI Card: Product Description (11/96)

=====

Article Created: 20 October 1996
Article Reviewed/Updated: 15 November 1996

TOPIC -----

This article contains the technical specifications for the Apple II SCSI card.

DISCUSSION -----

Technical Specifications
=====

Hardware

Provides an electrical interface between external SCSI devices and the CPU.

Provides the address and control lines required by the Apple II's microprocessor for accessing and controlling the SCSI chip and Smartport firmware.

Provides other circuitry to interface the 5380 IC with the Apple II CPU control signals.

NCR 5380 SCSI IC

Implements SCSI bus (5380 data sheet in Chapter 2 of the Hardware Technical Reference manual).

On board RAM

8 banks of 1K, accessed with special logic circuits. Used for status of devices at SCSI bus initialization (including the status of the Apple II SCSI card itself)

On Board ROM

8 banks of 1K, accessed with special logic circuits and used for storing Smartport firmware

Interface

25-pin SCSI connector

Input/Output

Parallel transmission, two modes for data i/o operations

- PDMA (pseudo-DMA), default
- Block Move only supported by 65816 CPUs and must be enabled by the application
- Maximum storage area under ProDOS: 32 megabytes

Firmware

Smartport program converts the microprocessor commands or calls issued by CPU to a format compatible with external SCSI devices

Issues calls to the microprocessor to give it the status of the external SCSI devices and allow the CPU to control their operation

Commands supported: STATUS, READ BLOCK, WRITE BLOCK, FORMAT, CONTROL, INIT, OPEN, CLOSE, READ, WRITE

Boot capability with Autostart ROM when you install the card in the slot with highest priority, which may depend on the operating environment

When Smartport does not find the SCSI device capable of starting up the system, Smartport returns control to the environment of the Apple II and the startup search continues through lower-priority slots.

Electrical

Voltage requirement: 4.75 to 5.25 volts DC

Power consumption in milliamps (ma)

Standby: 340 ma

Operating: 390 ma

Environmental

Ambient temperature: 50 to 104 deg F (10 to 40 deg C)

Relative humidity: 20 to 95 percent (non condensing)

System Requirements

Apple IIGS, Apple IIe or Apple II Plus

Apple II SCSI Card

Apple SCSI System Cable

One or more SCSI-compatible peripherals, can be a high-speed printer interface

Daisy chaining

Apple II with the SCSI card in slot 5 and ONLY a serial printer or modem card in slot 2.

- Running ProDOS 1.2: 4 external devices
- Running ProDOS 16: 7 external devices

Additional SCSI system components as required

Cable Terminator

Peripheral Cables

Cable Extenders (Maximum total length of cables: 20 feet (6.5 meters)).

Read the manual for the Apple SCSI Cable System before trying to connect any SCSI devices.

Using the DuoDisk with the Apple IIGS

Revised: 6/1/89
Security: Everyone

Using the DuoDisk with the Apple IIGS

=====

This article last reviewed: 04 May 1989

The DuoDisk can not be used as the last daisy-chained device on the built-in IWM disk port of the Apple IIGS. For instance, a UniDisk 3.5 will be rendered inoperable when the DuoDisk is installed in the above manner - although using the DuoDisk by itself is not a problem.

A qualified technician will have to modify the DuoDisk analog board if the DuoDisk is to be used as the last device on the chain. Please use the following procedure to determine how to modify the analog board.

Identifying Which Analog Board You Have

Remove the top cover as documented in Technical Procedures. Turn the drive so that the I/O connector is facing toward you. The identifying number will be at the bottom left of the analog board. The number might read 676-[]101, 676-[]102 or 676-[]107.

Performing the Modification

If the I.D.# for the analog board is 676-[]101 or 676-[]102, use a pair of nippers to cut out resistor R8 (located at position A2).

If the I.D.# for the analog board is 676-[]107, use a pair of nippers to cut out resistor R39 (located at position C3).

LaserWriter: Cause and Elimination of Image "Ghosts" (7/95)

Article Created: 11 August 1989
Article Reviewed/Updated: 28 July 1995

TOPIC -----

What causes of the ghosting effect on the LaserWriter printers? How can it be reduced or eliminated?

DISCUSSION -----

Overview and Recommendation

The most common type of ghosting problem exhibited by the LaserWriter is developer system ghosting. This form of ghosting is inherent in the design of the cartridge. In an effort to reduce or eliminate the ghosting problem, many alternate toners and cartridge designs were considered, but all of them would have substantially increased the cost of the printers.

The problem can be reduced by either increasing the copy density level (turning the print density dial counterclockwise or software density indicator if the printer is so equipped to a lower value) or by running several pages of the desired document (in many cases, the ghost image is reduced to acceptable levels by the third copy).

Detailed Explanation: the Causes of Ghosting

The xerographic process used in the LaserWriter has two major sources of ghost images:

- latent image on the photosensitive drum
- latent image on the developer cylinder

One source of ghosting is a latent image on the photosensitive drum. This results from either the failure of the cleaning system to remove a toner image from the drum, or failure of the drum preconditioning system to remove electrostatic image from the drum. It is also possible to "burn" an image into a

drum by exposing a drum, which has a toner image on the surface, to bright light for a long enough period of time.

The second source of ghosting is the image developer system. It manifests itself either as a darker or lighter ghost image in the solid areas of output copy.

The darker ghost is caused by the reduced ability of the toner, left for a period of time on the developer cylinder, to adequately develop the electrostatic image on the photosensitive drum. This reduced development capability results in a lighter image. Once replaced by more active toner from the toner supply bin, the image is noticeably thicker and darker. This effect can be seen when a solid black page is printed after the machine is allowed to sit unused for several minutes. In this case, the first two inches or so (one revolution of the developing cylinder) of the image will be lighter than the rest of the page.

This darker form of ghosting occurs when an image is created from the less active toner on the developer cylinder. The toner that was removed from the cylinder to develop the image on the drum, is replaced by the more active toner from the toner bin. Images formed on subsequent revolutions of the developer cylinder will be made of a combination of the more active and less active toners. These subsequent images will be dark where they are made by the active toner (remember that the active toner is in the shape of the earlier image which selectively removed the inactive toner) and lighter, where the less active toner is placed. This is why you see a dark "ghost" image approximately two inches from the original image, in what should be a uniform solid-area image. Of course, as the machine is run, more and more of the less-active toner is replaced by the more-active toner, resulting in decreased ghosting.

The visual effect of "dark" developer ghosting can also be diminished by increasing the print density. Because, once the paper is completely coated with toner, the paper no longer shows through to visually decrease the image density, increasing the print density to cover up the ghosting by making the light areas darker. Although the problem is still there, it is not as visible, and may be acceptable to the user.

The lighter form of developer system ghosting is caused by the lack of sufficient replenishing toner in the toner bin. It usually occurs as the toner supply in the cartridge is depleted. In this case, as above, toner is removed from the developer cylinder in forming a toner image on the drum. But, unlike the case above, there is a lack of toner in the bin to replace the lost toner on the cylinder. This results in a light form of ghost in the solid area parts of the output copy. With this form of ghosting, rocking the cartridge may be enough to redistribute the toner to the developer cylinder.

Because ghosting is affected by several other factors of environment and machine tolerance, you may notice different ghosting levels at various times during the year or from one machine to another.

Apple IIGS Adapter Cable: Pinouts

Revised: 10/12/87
Security: Everyone

Apple IIGS Adapter Cable: Pinouts

=====

This article last reviewed: 19 November 1986

Mini-8	Function	DB-25
1	HSKo --> DSR	6
2	HSKi <-- DTR	20
3	TXD- --> RXD	3
+--4	SGND --- SGND	7
5	RXD- <-- TXD	2
6	NC	8
7	GPI* <-- RTS	4--+
+--8	NC CTS	5--+
-	FGND NC FGND	1-----+
Shield	o-----o	Shield---+

Pins 4 and 8 are jumpered on the mini-8 side of the cable; pins 4 and 5 are jumpered on the DB-25 side of the cable as are pins 1 and the shield.

To connect DB-25 cables of Apple II family peripheral cables to the serial ports of the Apple IIGS, use the Apple IIGS Peripheral Adapter Cable. This short cable's male mini-circular 8 connector plugs into the IIGS printer and phone serial ports with the female mini-circular 8 connectors on the back of the IIGS. The DB-25 connector at the other end of the adapter cable will take the DB-25 connectors of the DB-25 cables used with many Apple peripherals.

Some modems and communications software may need a DCD signal and therefore

may require a modem eliminator cable in the cable configuration. The modem eliminator cable flips pins 2 with 3 and 6 with 20 and passes GPi access through to pin 8. GPi, for General Purpose input, is a high or low signal read from and determined by the connecting device.

Access II: Configuring version 1.2 on an Apple IIGS

Revised: 5/25/89
Security: Everyone

Access II: Configuring version 1.2 on an Apple IIGS

=====

Apple has issued an upgraded version of Access II for support of the Apple IIGS internal modem port.

While version 1.2 is essentially the same as the previous version of Access II, successfully using version 1.2 constrains the IIGS system in the configuration of slots 1 and 2. Access II works properly when slots 1 and 2 are set up in their default configurations from the Control Panel:

Under the 'SLOTS' menu item:

Slot 1: Printer Port
Slot 2: Modem Port
Slot 7: Your Card

Under the 'Modem Configuration' menu item:

Device Connected: Modem

Unless the following change is made to the default settings of the modem port, Access II will freeze and no dialing will occur.

1. enter the Control Panel
2. select Modem Port
3. select DCD Handshake: it MUST be answered NO
4. select DST/DTR Handshake: it MUST be answered NO
5. tap the RETURN key to save your change.

Be sure to turn the computer off before trying Access II again.

The Modem Port setting should look like this:

Device Connected: Modem
Line Length: Unlimited
Delete first LF after CR: No
Add LF after CR: No
Echo: No

Buffering: No
Baud: 1200
Data/Stop Bits: 8/1
Parity: None
DCD Handshake: No
DSR/DTR Handshake: No
XON/XOFF Handshake: No

When using Access II 1.2 through the IIGS internal port, there cannot be any type of interface card in slots one or two, regardless of control panel settings. If they are present, various results may be encountered including the Utilities function of the program becoming inaccessible.

Also, if you are using AutoDial to dial out, you must wait about 30 seconds before you will hear a dial tone and the number dialed. If after 30 seconds you don't hear the dial tone, check the cable connections and settings of the IIGS Control Panel and Access II and try again.

AppleWorks 2.0: Features

Revised: 6/9/87
Security: Everyone

AppleWorks 2.0: Features

=====

The designers of AppleWorks have changed features in version 1.3 with AppleWorks 2.0:

1. File size limits

When a one megabyte Apple Memory Expansion card (or its Apple IIGS or IIc equivalent) is installed, AppleWorks 2.0 has the capacity for the following file sizes:

-- Database records: 6350 (instead of 1350)

6350 is the maximum number of records that can be placed in the AppleWorks data base with only 1 field identified with 1 character and having entries of only 1 character. Using an Apple II with a 1 megabyte memory board, you can add 6350 records. You will find there is still plenty of memory available, but AppleWorks will tell you the data base has reached the maximum number of records permitted.

On the other hand, on a data base pushed to the maximum of 30 fields, each with a length of 20 characters and filled by 17, you will find that you will run out of desktop memory before the data base reaches the maximum record count.

-- Word processor lines: 7250 (instead of 2250)

-- Spread sheet rows: 10K (instead of 1.55K)

2. Automatic RAMDisk pre-load

When an Apple Memory Expansion card (or its Apple IIGS or IIc equivalent) is installed, AppleWorks 2.0 will automatically pre-load into the RAMDisk as a part of the boot process. This pre-loading takes only about 30 seconds and may be halted by pressing the ESC key.

All AppleWorks files except the SEG.PR file are loaded into the RAM card on startup. The SEG.PR file contains only printer data, and, because of its

small size, it would be one of the first files to be removed from memory if a file needed that space.

One possible way around this is from the Control Panel:

Set aside 192K for a RAMDisk in the memory expansion area. Copy AppleWorks into the RAMDisk with System Utilities. Then go into BASIC, and run APLWORKS.SYSTEM from the RAMDisk. Appleworks will load itself into memory while recognizing the RAMDisk. Now, when the program requires the SEG.PR file, the program, retaining the fact that it started up from the RAMDisk, goes there to find the SEG.PR file.

3. New Spreadsheet feature: Cut/Copy & Paste:

After a cell has been cut or copied to the clipboard, the user will be able to paste from the clipboard either the value, the formula, or both.

4. New file save feature:

If there is not enough room on a disk to save a file that already exists on the disk, then AppleWorks first allows the user to delete the original file from the disk. With AppleWorks' capability to create larger files, this feature will become important.

5. Enhancements and fixes:

a. Word Processor:

- Removed code that made the word processor take 13 seconds to process a carriage return in the middle of the first paragraph of a 2000 line document.
- Inserted extra code to make ESC and some OPEN-APPLE keystrokes work faster on large documents.

b. Spreadsheet:

- The routine to display spreadsheet rows was changed; it should now work faster on rows that have lots of filled cells.

Apple Equipment: Using On 12 Volts (2/97)

Revised: 2/18/97
Security: Everyone

Apple Equipment: Using On 12 Volts (2/97)

=====

Article Created: 19 November 1986
Article Reviewed/Updated: 13 February 1997

TOPIC -----

This article discusses using Apple equipment with a 12V DC power supply.

DISCUSSION -----

Apple Computer, Inc. is not responsible for any damages, real or implied, resulting from the use of this information. The responsibility for any damage lies completely with the user.

If you want to use Apple equipment on 12V DC, bear in mind the following precautions prior to powering up.

An inverter is a power converter that takes a direct current voltage, commonly 11.4 to 14.4 volts DC, and changes it to a nominal 120 Volts AC. Care must be taken to ensure an adequate supply of direct current to the inverter so the output voltage will be within the normal requirements of the attached equipment. This means that the minimum power capability of the converter would have to be at least 50% higher than the combined maximum current of the attached equipment.

Example: To connect a Macintosh Plus and an ImageWriter II to a 12v inverter, the maximum current draw of the equipment is 300 watts. The minimum safe rating of an inverter would be 450 watts, and 500-600 would be better. This allows a high enough safety factor so the inverter will not overheat, and the current draw will not be high enough to drop the AC output voltage.

The majority of the inverters on the market output the AC power as a square wave. Most Apple CPUs use switching power supplies which can handle this square wave power without any difficulties. However, square wave power causes the equipment to generate more than the normal amount of heat. You can eliminate the cause, the high frequency component of the square wave, by placing a line filter between the square wave power source (the inverter) and the attached equipment

to provide a modified sine wave. The filter doesn't reduce the power but does soften the waveform enough to minimize the effect of abnormal heat. The line filter should have a current (or power) rating equal to the rating of the inverter. While a matching filter is not absolutely necessary, it should be considered if the life of the equipment is a factor.

Damage to the equipment can occur when too much heat or too little power is running through the system. Be very sure to observe power and current ratings to match an inverter to any electronic equipment so that the inverter will supply the proper amount of power.

Powering computer equipment with an inverter gets you and your computer into many different environments: boats, planes, trains, as well as some solar powered homes, and other places that previously could not support electronic equipment.

Apple IIC: 80/40 switch

Revised: 11/19/86
Security: Everyone

Apple IIC: 80/40 switch

=====

The 80/40 switch on the Apple IIC only sets a bit in memory. While a program can read this bit and use the setting in a decision to display 80 or 40 columns, in practice, only a few programs, e.g. Apple Writer, take advantage of the switch in that way. In itself, the 80/40 switch does not force 80 column firmware on or off; only a software command like Applesoft's PR#3 or PR#0 can do that.

The 80/40 switch on the Apple IIC was designed for customers who use their television set as a monitor. A television set doesn't display 80 columns of text very legibly; 40 columns reads much better. Unfortunately, most Apple II software packages, written before the Apple IIC, don't check the bit set by the 80/40 switch.

Because the bit setting is independent from the PR#3 command, programmers can use the bit set by the 80/40 switch for features other than 80/40 column display:

```
10    TEXT:HOME:REM INITIALIZATION
100    SWITCH = PEEK(49248):REM MEMORY LOCATION FOR CURRENT SWITCH SETTING
110    VTAB 12
120    IF SWITCH > 127 THEN PRINT "80/40 SWITCH DOWN":REM OR ANYTHING ELSE
130    IF SWITCH < 128 THEN PRINT "80/40 SWITCH UP ":REM OR ANYTHING ELSE
140    GOTO 100
```

For more info, see the two-volume Apple IIC (16K ROM) Technical Reference Manual, pages 5 and 77 of Volume I and page 128 of Volume II, or the one-volume manual published by Addison-Wesley, pages 5, 80, and 342.

Apple II SCSI Card: Interrupt Problem (11/96)

Revised: 11/21/96
Security: Everyone

Apple II SCSI Card: Interrupt Problem (11/96)

Article Created: 26 November 1986
Article Reviewed/Updated: 15 November 1996

TOPIC -----

This article discusses a potential problem with the Apple IIGS, Apple II SCSI card and programs using interrupts.

DISCUSSION -----

Apple IIGS system crashes may occur with programs using interrupts during access of SCSI disk drives connected to the Apple II SCSI card. Once interrupts are enabled, it is possible an interrupt may occur during a SCSI drive data transfer. Programs initiate data transfer by passing control to the SCSI card.

The SCSI card firmware places code in its own stack for executing. If taking an interrupt also places code on the same stack it may wipe out some or all of the previous SCSI firmware code. Returning from the interrupt, returns to the portion of the stack corrupted by the interrupt, which results in some kind of unidentifiable system crash.

Crashes are possible if BOTH of the following conditions apply:

- The SCSI card is used with an interrupt driven program, like AppleTalk.
- This application program calls the SCSI card directly, NOT using ProDOS.

To work around this possibility, make sure your applications use ProDOS to handle any interrupts. This may decrease SCSI disk data transfer rates but will help reduce system crashes.

Apple IIGS: Printing to the LaserWriter from AppleWorks

=====

Article Created: 26 November 1986
Article Last Reviewed: 23 April 1991
Article Last Updated: 23 April 1991

The following instructions are valid for AppleWorks versions 1.3 and 2.0; earlier versions of AppleWorks have not been tested with these modifications. These changes support both the LaserWriter and the LaserWriter Plus.

You first create an AppleWorks program disk with all the files required to print AppleWorks documents to the LaserWriter and thereupon you test the disk by printing a document.

Then you can create a bootable disk that effectively reduces the number of manual steps needed to prepare the system for printing your AppleWorks documents to the LaserWriter.

Creating a program disk:

Using the System Utilities program,

- Name a disk /APPLEWORKS. For this set of instructions, we'll say the disk is a single 3.5" disk.
- Copy all files from the master AppleWorks disk to the single 3.5" disk you have named /APPLEWORKS.
- Put away the master AppleWorks disk
- Delete the old version of ProDOS 1.1.1 from your /APPLEWORKS disk.
- Copy the new version of ProDOS, P8, from the Apple IIGS System Disk to your /APPLEWORKS disk.
- On your AppleWorks disk, rename P8 with the name PRODOS.

-- Copy the following files from the Apple IIGS System Disk to your
/APPLEWORKS disk:

```
ATINIT ----- AppleTalk initialization program
IWEM ----- ImageWriter Emulator program
MTXABS.0 ---- Mousetext tool kit
NAMER.0 ----- Namer Object Code
NAMER.II ---- Namer program
CHOOSE.0 --- Chooser Object Code
CHOOSE.II -- Chooser program
```

Printing a document with AppleWorks and the LaserWriter:

You need only do steps 3a through 3f once; after that, the disk has the necessary information.

1. Plug the AppleTalk cable into the printer port on the back of the Apple IIGS.
2. Change the Control Panel Slot settings to "Your Card" for Slot 1 and to "Built-In AppleTalk" for Slot 7. (Note: If you have the newer model Apple IIGS with 1MB of RAM on the logic board, set Slot 7 to AppleTalk and EITHER slot 1 or slot 2 to AppleTalk.)
3. Tell AppleWorks how to send information to the LaserWriter:
 - a. Start up AppleWorks and choose Other Activities from the Main Menu (item #5).
 - b. Choose Specify information about your printer(s) (item #7).
 - c. Choose Add a printer (item #2).
 - d. Choose Apple ImageWriter.
 - e. To name the printer, type "LaserWriter" and press Return.
 - f. Choose Slot 7.
4. Start up the application called Chooser on your System Disk.
5. Click on LASERWRITER and choose the LaserWriter to which you want to print.
6. Quit Chooser.
7. Start AppleWorks by typing:

```
-/APPLEWORKS/APLWORKS.SYSTEM
```

Note: The Chooser and the ImageWriter Emulator

The Chooser program "CHOOSER.II" must be run and the LaserWriter selected each time your LaserWriter is turned off and on. The CHOOSER program is used to download the IWEM file from the Apple IIGS into the LaserWriter. If the LaserWriter has been powered off since the last time the IWEM program was downloaded, the AppleWorks program will not print to the LaserWriter.

A problem surfaces when a network only has one AppleTalk device available at the time of a Chooser boot. The very first time you boot the Chooser and select the LaserWriter, it will download the emulator and everything will work fine. The problem starts when the Chooser saves the user name and last selected printer to disk: when you re-run the Chooser, the one and only LaserWriter is already selected and won't let you click on it again to re-download the ImageWriter Emulator.

This has been fixed in Chooser 1.1. The only AppleTalk device that is available allows you to 're-click' on it to load the ImageWriter Emulator.

Creating a bootable disk:

To run the Namer, Chooser, or AppleWorks at boot time, create the simple startup program below and copy it to the disk. Follow the file copying instructions above in "Creating a program disk," and then:

1. Using the System Utilities

- Copy the file BASIC.SYSTEM from the Apple IIGS System Disk to your AppleWorks disk.
- On your AppleWorks disk, rename the file called APLWORKS.SYSTEM to APLWORKS
- Exit to BASIC

2. Create the following Applesoft BASIC program:

```
10 HOME : REM  Startup program
20 PRINT " Program Loader ": PRINT
30 PRINT " 1) AppleWorks "
40 PRINT " 2) Chooser"
50 PRINT " 3) Namer": PRINT
60 INPUT " Enter your choice:";A$
70 A = VAL (A$)
80 ON A GOTO 100,200,300
90 GOTO 10
100 PRINT CHR$ (4);"-APLWORKS"
110 END
200 PRINT CHR$ (4);"-CHOOSER.II"
210 END
300 PRINT CHR$ (4);"-NAMER.II"
310 END
```

3. Check to be sure you entered the BASIC program exactly as shown.

4. Type SAVE STARTUP and press Return.

Boot your AppleWorks disk; the following appears on the screen:

Program Loader

- 1) AppleWorks
- 2) Chooser
- 3) Namer

Enter your choice:

Type in the number of the program you wish to run, and press Return.
Whenever you print to "LaserWriter," your output will be directed to the
last LaserWriter chosen using Chooser.

ProDOS 1.1.1: Incorrectly Displays 1982 as the Current Year

=====

This article last reviewed: 19 January 1988

ProDOS 1.1.1 has problem with dates after 1987. One result is that when you set the date in AppleWorks, then you turn off the computer and back on again, the displayed date is correct except the year is shown as 1982 rather than 1988.

If you upgrade the ProDOS on your startup disks to ProDOS 1.4, this problem should disappear.

AppleWorks: Getting 10 CPI single spaced on the LaserWriter

Revised: 12/11/86
Security: Everyone

AppleWorks: Getting 10 CPI single spaced on the LaserWriter

=====

The Diablo emulation mode command string

ESC, CTRL-Underscore, CTRL-M

for 10 characters per inch becomes a problem when used with conventionally configured AppleWorks. The code sets the LaserWriter to 10 CPI, but because the Super Serial Card firmware includes a Line Feed as it picks up the CTRL-M, it adds a line feed to each line: single space text comes out double spaced, double space triple spaced, etc, making single spacing in 10 characters per inch impossible.

In order to fix this problem, tell AppleWorks to insert the linefeeds and configure the serial card NOT to add linefeeds by setting switch SW2-5 to OFF. For the built-in serial port in an Apple IIGS, use the Control Panel; for the printer port of the Apple IIc, use the Apple IIc System Utilities. AppleWorks will be smart enough not to insert linefeeds after any carriage returns in the printer codes.

LocalTalk: Soldering connectors of the Custom Cable Kit

Revised: 11/2/88
Security: Everyone

LocalTalk: Soldering connectors of the Custom Cable Kit

=====

This article last reviewed: 11 December 1986

Intermittent network problems can result from bad electrical contact caused by residual solder flux on Custom Cable Kit connectors. After the connectors are dis- and reconnected a few times, the network problems no longer appear, but the users of the network are wary and unconfident.

Assemblers of Custom Cable Kit networks can avoid this situation by 'flushing out' any residual flux from the male connector end after assembly. Caution must be exercised in doing this as most commonly used flux removal solvents destroy the plastic connector assembly. A remedy is a silicon-based spray 'contact enhancer' called "TWEED", from UKO Inc., Berkeley, CA. Any other type of contact cleaner or enhancer can be used, as long as it does not have any solvent in it.

Not machined into its pin shape, the connector is instead stamped and rolled, leaving a small channel along the length of the pin. Solder flux flows in this channel and a small portion enters the contact area of the male connector when the AppleTalk wire is soldered to the open side of the pin. Once the flux is on the contact area of the pin, the flux inhibits contact with the female connector, and this partial connection gives intermittent network problems.

Apple IIGS Errors: Toolset numbers

Revised: 12/11/86
Security: Everyone

Apple IIGS Errors: Toolset numbers

=====

Generally, error numbers are a hybrid of the toolset number and a specific error within that toolset: the first byte is the tool number and the 2nd byte, the error number.

For example, error \$110B is an error that occurred within the Segment Loader (\$11 in decimal is 17). Specifically, error \$110B is a 'Load Segment is Foreign' error, which can occur from the Initial Load (function \$07) or Load Segment by Number (function \$09) calls.

Here, you can at least identify in which Toolset an error occurred with this list of current Tool Sets and their Toolset numbers (to be superceded by an APDA mailing).

- 1 - Tool Locator
- 2 - Memory Manager
- 3 - Miscellaneous Tools
- 4 - QuickDraw //
- 5 - Desk Manager

Apple IIGS Monitor: Step, Trace, and Search

Revised: 10/12/87
Security: Everyone

Apple IIGS Monitor: Step, Trace, and Search

=====

This article last reviewed: 11 December 1986

Step and Trace are not built into the Apple IIGS Monitor.

The format for the search command is

```
\<search string>\{<bank>/}<addr1>.<addr2>P
```

where <search string> is either a series of hexadecimal values or ASCII text delimited by single or double quotes. In addition, the entire search string is separated from the search range with backslashes. <Bank> is optional (as the braces are meant to indicate) and specifies the memory bank in which you want to search. If you do include a bank number, then you must separate it from <addr1> with a slash. <addr1> and <addr2> are the start and end of the memory range of the search.

For example, to look for the location of the Apple IIgs startup message, type:

```
\ "Apple IIgs" \FF/0000.FFFFFP
```

You should get

```
FF/F914:
```

as the response.

AppleWriter II (ProDOS): Printing from an Apple IIGS

=====

The Applewriter program works fine on the Apple IIGS until the program locks up when you try to have it print through the Apple IIGS's serial ports. If a Super Serial Card with an ImageWriter or an ImageWriter II with an AppleTalk option is used, AppleWriter prints fine. The problem occurs with prints to the internal Apple IIGS serial ports. AppleWriter may address and only address the Super Serial Card's communications chip and not the Apple IIGS's communications chip.

AppleWorks: Lining up amounts in a Spreadsheet

=====

Numbers in Dollar format misalign in columns

\$45.66	\$78.99	\$55.33
98.66	33.45	23.99
44.55	14.75	34.76
23.56	44.89	34.66

because AppleWorks makes space for signifiying negative amounts with parentheses:

(\$45.66)	(\$78.99)	(\$55.33)
98.66	33.45	23.99
44.55	14.75	34.76
23.56	44.89	34.66

To get the remaining numbers to line up with the 'Dollar' formatted numbers, use the 'Commas' format, which makes space for the same parentheses but doesn't display a dollar sign:

\$45.66	\$78.99	\$55.33
98.66	33.45	23.99
44.55	14.75	34.76
23.56	44.89	34.66

MacDraw 1.9, 1.9.5: Printing Without Page Breaks

=====

Article Created: 11 December 1986
Article Last Reviewed: 31 March 1992
Article Last Updated: 31 March 1992

TOPIC -----

The following discusses printing with MacDraw 1.9 and 1.9.5 without page breaks.

DISCUSSION -----

When its rulers are set to centimeters, MacDraw 1.9 and 1.9.5 put a break between pages even though you select "No Breaks Between Pages".

You can work around this by drawing your document in the normal manner and changing the ruler increments to inches just before printing. MacDraw then prints without page breaks.

New Ground Wire to HyperDrive Bracket

Revised: 1/7/87
Security: Everyone

New Ground Wire to HyperDrive Bracket

=====

The current DC power supply harness of the HyperDrive 20 has a green ground wire on the line to the hard disk assembly. This green wire should be attached to the small spade on the silver DRIVE BRACKET surrounding the drive and not to any spade you might see on the drive itself. If there is no spade on the bracket, the ground wire should be snipped off.

AppleWorks: Desktop size on the Apple IIGS

Revised: 1/20/87
Security: Everyone

AppleWorks: Desktop size on the Apple IIGS

=====

For desktop storage, AppleWorks 2.0 on an Apple IIGS will only use memory found on the Apple IIGS logic board and Memory Expansion Card. When this card is not present and AppleWorks 2.0 is booted from the Apple IIGS System Disk, the Apple IIGS Tools, using a large portion of available logic board RAM, leave only 13K for the AppleWorks desktop. The message "WARNING! Desktop is full. Action not completed. Press space bar to continue." appears when the user attempts to create a word processor file from scratch. If you make a second attempt to create a word processor file, AppleWorks will complete the task.

AppleWorks' users should be aware of this situation before using AppleWorks 2.0 and the Apple IIGS System Disk files on an Apple IIGS without an Apple IIGS Memory Expansion Card installed.

If AppleWorks 2.0 is booted from the AppleWorks Startup Disk, an Apple IIGS 1M Expansion Card will permit up to 1149K on AppleWorks' desktop. Factors that affect the size of AppleWorks' desktop are:

- memory available on the Apple IIGS Memory Expansion Card
- memory occupied by the Apple IIGS RAM disk
- the availability of the Apple IIGS desktop
- other AppleWorks auxiliary programs that are loaded into the Apple IIGS
- the method used to start up AppleWorks.

You may create a disk that will allow AppleWorks and the Apple IIGS Desktop to be used effectively on the same disk:

1. Make a new copy of your AppleWorks 2.0 master disk.
2. Remove the file "PRODOS" from the new AppleWorks disk.
3. Copy the file called "P8" from the System folder on the Apple IIGS System Disk onto the new AppleWorks disk. Rename the copied file "PRODOS". The disk is now bootable for starting up the Apple IIGS.

If you wish to add the desktop:

1. Locate the folder "DESKTOP" on the Apple IIGS System Disk.
Copy the contents of this folder onto the root directory of the new AppleWorks disk.
2. On new the AppleWorks disk, rename the file "APLWORKS.SYSTEM" "APPLEWORKS" and "DESKTOP1" "DESK1.SYSTEM".
3. Start your Apple IIGS with the modified AppleWorks disk.
Once the desktop appears, double click on the "APPLEWORKS" icon to run the AppleWorks program. Using this disk on an Apple IIGS with 256K memory provides 124K of AppleWorks' desktop space.

AppleWorks versions 1.1, 1.2 and 1.3 can be used on an Apple IIGS, an Apple IIc, or an Apple IIe with either 64K or 128K memory. AppleWorks' desktop size on an Apple IIGS will vary with the version of AppleWorks in use. Because AppleWorks 1.3 and earlier versions do not recognize the newer features of the Apple IIGS, the user can obtain only a 55K AppleWorks desktop, even though the computer may have from 256K to 1.25M of memory on the logic board and in the Memory Expansion Slot. However, if the Apple IIGS has an Apple II Memory Expansion Card in one of its seven slots, AppleWorks 1.3 does recognize it and uses the Memory Expansion Card to increase the desktop size.

Security: Everyone

Apple IIGS: Composite and analog video

=====

This article last reviewed: 20 January 1987

The Apple IIGS has two video ports: an RCA phono jack and a 15-pin D-Type connector. An EIA-standard composite video signal (2.0V white, 0.75V black, 0.0V sync., 75-ohm impedance) is available from both connectors. This composite signal drives many monitors such as the AppleColor Composite Monitor, the Apple Monochrome Monitor, and a TV unit with an RF modulator. While composite video monitors can be used with the Apple IIGS, they don't fully render the 320 x 200- and 640 x 200-pixel color graphics potential of the new system.

The 15-pin connector analog RGB signals provide full color graphics display capability. Note that the Apple IIGS outputs analog, not digital, RGB signals. The designers preferred the unrestricted character of an analog signal for the ability of the Apple IIGS to support 4096 colors. Apple offers a new platinum Apple Color RGB Monitor for the Apple IIGS. Other analog RGB monitors known to work with the Apple IIGS include several models by Hitachi, Panasonic, Sanyo, Mitsubishi, Conrac, and Commodore.

To check if your monitor is analog RGB, consult the manual. Check the pinouts before connecting the monitor to an Apple IIGS to make sure your monitor is compatible with pins 7 and 8. The Apple IIGS's 15-pin RGB video signals are as follows:

Pin	Signal
-----	--------

- | | |
|---|------------------------|
| 1 | Signal ground (Red) |
| 2 | Analog RED with sync |
| 3 | Composite sync |
| 4 | No connection |
| 5 | Analog GREEN with sync |
| 6 | Signal ground (Green) |
| 7 | -5 volts DC |
| 8 | +12 volts DC |
| 9 | Analog BLUE with sync |

10	No connection
11	Sound 1V peak-to-peak
12	NTSC/composite color video out
13	Signal ground (Blue)
14	No connection
15	No connection
Shield	System ground

There's no simple, straightforward way to invert sync or to separate horizontal and vertical sync on the composite signal for incompatible monitors, but it could be done as an interface product.

Some types and makes of monitors won't work at all. Digital RGB monitors either won't work at all or will work with unpredictable results. Digital RGB monitors with these problems are Apple's older Color Monitor 100 and IBM RGB monitors (IBM's RGB monitors need inverted sync in addition to TTL video signals.). Apple's Flat Panel Display has incompatible signals.

Do NOT assume that a DB-15 connector on your color monitor means it's analog RGB.

ProDOS 1.1.1: Track 0 not automatically protected

=====

In ProDOS 1.1.1 and ProDOS 8 v1.2, part of the Disk II I/O driver code causes occasional trashing of track 0.

ProDOS 8 v1.3 and 16 were changed to solve this problem, first reported in the January 1986 issue of Open Apple. An Applesoft solution appears in the November 1986 issue in an article entitled "ProDOS bug found in Australia".

The beginning code of the driver performs a series of instructions intended to de-activate any UniDisk 3.5's that may happen to be on line. The problem occurs when these instructions cause a clash on the disk drive port data lines. The clash may put in write mode any 5.25" disk drive (Disk II, UniDisk, Apple 5.25, DuoDisk, or Apple IIc external drive). ProDOS 1.1.1 and ProDOS 8 v1.2 do not check for this re-setting, so they act as if the 5.25 drive were in the read-only state (which it is under normal circumstances). The next time these versions of ProDOS attempt to access a 5.25 disk, they wipe out what they would normally read. In many cases, the directory is wiped out because many applications check the directory in order to open a file.

LaserWriter: Memory requirements for downloadable typefaces

Revised: 9/12/88
Security: Everyone

LaserWriter: Memory requirements for downloadable typefaces

=====

This article last reviewed: 28 January 1987

The amount of LaserWriter RAM required for Adobe typefaces are given below.

When a LaserWriter receives its first downloadable typeface file, memory is loaded with information that is global to all the typeface files. This happens just once and takes, at most, 10K of LaserWriter RAM.

After the first typeface file is sent to the printer with the extra global information, all following typeface files will only take the amount of approximated memory shown below.

Note that Oblique faces have two numbers associated with them: the first represents the amount of memory used if the main face has been previously downloaded (such as the Roman version of that face), and the second number represents memory taken if the main face does not reside in memory, although you may need to account for the one-time-hit mentioned above.

Adobe downloadable fonts, with memory required (in bytes):

	Roman	Light	Medium	Bold	Demi	Book
ITC American Typewriter			33K	34K		
ITC Avant Garde Gothic					22K	21K
Oblique					3K/26K	3K/26K
ITC Benguiat				26K		25K
ITC Bookman		25K			25K	
Italic		26K			25K	
ITC Friz Quadrata				25K		
(Regular - 24K bytes required)						
ITC Garamond		33K		35K		
Italic		33K		35K		
ITC Glypha	23K			25K

Apple IIf Owner's Manual 030-1030-B: Erratum on PR#7 feature

=====

Received with the new Apple IIf, the manual with part number 030-1030-B shows, at the top of page 100, how to boot the computer off the external drive as part of a troubleshooting procedure.

However, the manual doesn't state that the PR#7 feature has been removed since the introduction of the UniDisk 3.5 option for the IIf.

Applesoft BASIC: Making a text file from a program file

Revised: 1/28/87
Security: Everyone

Applesoft BASIC: Making a text file from a program file

=====

To transfer a program in Applesoft BASIC from the Apple II family of computers to another computer, you must first make a text file from the program. Adapt to your own situation this example:

Assume that your BASIC program begins with line number 10 and ends with line number 30000. Add these lines to the beginning of the program:

```
1  PRINT CHR$(4);"OPEN TEXTFILE"  
2  PRINT CHR$(4);"WRITE TEXTFILE"  
3  LIST 10-30000  
4  PRINT CHR$(4);"CLOSE"  
5  END
```

Save the program with the new lines added, then run the program.

This will work in DOS 3.3 or ProDOS, so long as either was used to boot the disk, and so long as there is disk space available to write the program file.

If your program has used lines 1-5, put the new lines at the end, as lines 30001-5 for example, and then type RUN 30001.

ImageWriter: Codes for printing accented vowels

Revised: 4/2/87
Security: Everyone

ImageWriter: Codes for printing accented vowels

=====

To print an accent mark over a vowel in an AppleWorks word processor document, you can backspace and print an accent.

Or you can use the command

`e<superscript>'<normal>`

You must, however, turn on superscripting with command sequences you define in the custom driver.

With ImageWriter, you can use the following sequence of characters to turn on superscripting:

`CTRL-H ESCAPE ESCAPE ll ESCAPE T12 ESCAPE r CTRL-_ 1`

(N.B. ESCAPE ll is ESCAPE, lower case L, numeric one)

The characters needed to end superscripting are:

`ESCAPE T09 ESCAPE f CTRL-_ 1 ESCAPE A ESCAPE 10`

(N.B. T09 and 10 have numeric zero)

ESCAPE T09 compensates for the "printer slop" that the tractor feed causes when a reverse linefeeds occurs. If you are using friction feed, these codes are not necessary and may be removed.

If you are using an ImageWriter II, then the superscripting control codes are easier:

`CTRL-H ESCAPE ESCAPE x`

To end superscripting, use:

`ESCAPE z`

Character sets available on the Apple IIGS and ImageWriter may be of some help. For instance, Italian has an accented 'e'. Check the ImageWriter II manual, Appendix C, for a list of the characters in the character sets.

One of the options in the Apple IIGS is the ability to change the characters set of the display and the keyboard layout. By entering the control panel, and selecting "Display: Spanish", you will be able to display certain Spanish characters that print properly when sent to an ImageWriter in Spanish mode.

Apple IIGS: Error in Show Text File Desktop Accessory

=====

This article last reviewed: 4 February 1987

On version 1.1 of the Apple IIGS System Disk, dated December 2, the Apple II DeskTop gives a "system error" when the desk accessory Show Text File comes to end-of-file. This doesn't happen with version 1.0, dated November 26.

Furthermore, on both versions, 1.0 and 1.1, of the system disk, this desk accessory will only show the first 32K of a text file.

Apple IIGS: Grappler Plus cards

=====

This article last reviewed: 4 February 1987

Older Grappler Plus cards are not necessarily Apple IIGS compatible. Some of the older interface cards malfunction because of timing changes made to the IIGS slots, even though these changes were within Apple's specifications. The Grappler Plus card was designed before Apple even had those timing specifications.

On the Grappler Plus card at location U10, if the chip there is a 74LS373, then you have an old card and should contact Orange Micro. A 74LS374 is at U10 on the recent card.

AppleWorks 2.0: Printing to disk

Revised: 2/4/87
Security: Everyone

AppleWorks 2.0: Printing to disk

=====

When printing to disk, AppleWorks 2.0 only saves a document in this way with carriage returns ending each line (by selecting the Silentype printer option).

If you need to workaroud this situation, the text file printed to disk by AppleWorks can be read into AppleWriter or a BASIC program. You can then replace all spurious carriage returns with spaces, taking care to recognize and preserve carriage returns at the end of paragraphs.

The feature of putting a carriage return at the end of a line was added because many people had problems transmitting text with lines longer than 255 characters.

All previous versions of AppleWorks printed to disk a file with carriage returns only at the ends of paragraphs.

Apple IIe: Keyboard and keypad in Apple IIGS upgrades

Revised: 10/12/87
Security: Everyone

Apple IIe: Keyboard and keypad in Apple IIGS upgrades

=====

This article last reviewed: 6 February 1987

When upgraded to an Apple IIGS, two different Apple IIe systems will behave exactly the same as the Apple IIGS: an Apple IIe with an external numeric keypad and a new Apple IIe with built-in numeric keypad. The "ESC" is mapped as a "Clear" on both systems. Remember, you still have extra keys on the IIe numeric pad.

Once an Apple IIe is upgraded, the keyboard behaves the same as the Apple IIGS keyboard. Remember, the Solid Apple Key is now the 'Option' key. Since there is a place on the motherboard labeled "NUMERIC KEYPAD", a connected keypad behaves the same as on the Apple IIGS keypad and then some. It is, of course, laid out differently, but all the keys that are on the IIGS keypad are on the IIe keypad. The extra keys available are: space, comma, "(", ")", and the left and right arrows. The "ESC" key is now the IIGS "Clear" key, and the "Print key" is now an "=".

An Apple IIe with a keyboard and keypad connected to an Apple IIGS motherboard in the upgrade does not affect operation of the Apple Desktop Bus. The DeskTop Bus continues to operate fine, regardless of what is hooked up via the Keyboard or Numeric pad connectors. It is possible to have both new and old keyboards hooked up and functional at the same time.

Apple IIGS: Keyboard Connector

Revised: 11/10/88
Security: Everyone

Apple IIGS: Keyboard Connector

=====

This article last reviewed:10 November 1988

A problem concerning the connectors present on release Apple IIGS motherboards comes out of the fact that certain Special Education devices require the use of the keyboard connector (not the Game I/O) for different input devices.

The keyboard connector sockets aren't mounted on the Apple IIGS motherboard in the systems that will ship to customers; the connectors only are mounted on Apple IIGS IIe upgrade boards.

Depending on size of order, Manufacturing may do a special Apple IIGS build with keyboard and numeric keypad connectors. You should have your Sales Representative go through normal channels to investigate.

On a single unit basis, there is no way for Apple to add the connectors to an Apple IIGS board. However, all of the electronics for the external keyboard connectors exists on current Apple IIGS units. If you can find the connectors, it is possible to solder them in.

Apple IIGS: Desk Accessories

Revised: 9/22/89
Security: Everyone

Apple IIGS: Desk Accessories

=====

This article last reviewed: 17 February 1987

At startup, Apple IIGS Desk Accessories are automatically installed by ProDOS. It scans the sub-directory SYSTEM/DESK.ACCS on the startup disk for any files of type \$B8 (CDA) and installs them. A CDA is a classic desk accessory, a menu of which can be accessed with Command-Control-Escape.

The format of a CDA is very similar to that of a regular application. The main difference is the existence of a header that contains:

- a Pascal string that contains the name of the CDA
- a pointer to the entry point of the CDA code
- a pointer to the shutdown routine of the CDA code

More documentation on writing classic and new desk accessories will be found in the chapter on the Desk Manager in the Apple IIGS Toolbox Reference Manual in summer 1987.

Apple IIGS: Controlling speed mode from machine language

Revised: 2/17/87
Security: Everyone

Apple IIGS: Controlling speed mode from machine language

=====

In the Configuration Register, CYAREG, at location \$C036, the bit to control is the high bit: setting it to 0 will set the normal mode and setting it to 1 will put the Apple IIGS in fast mode. The following machine language program shows how to use the bit.

```
300: lda C036
303: jsr FDDA    ;print the value of the memory location
306: jsr 0318    ;wait a little while
309: lda C036    ;now swap the speed mode
30C: eor #80
30E: sta C036
311: jsr FDDA    ;and show how it changed
314: jsr 0318    ;wait again, to show the speed difference
317: rts

318: ldx #00     ;this is a wait routine that will pause for 8 seconds
31A: ldy #00     ;in fast mode, and 19 seconds in normal mode
31C: jsr 031F
31F: jsr 0322
322: jsr 0325
325: jsr 0328
328: jsr 032B
32B: jsr 032E
32E: dex
32F: bne 032E
331: dey
332: bne 032E
334: rts
```

This program will print the value of CYAREG, pause a while, flip the speed, print the new value of CYAREG, and wait again. The speed difference is very apparent.

Take note that speed control under AppleSoft may be very difficult, if not impossible. Many firmware routines need the speed mode changed, so they often save the previous mode on the stack and then set the required speed mode. In

this case, if you set the speed from AppleSoft or directly from the monitor, the speed mode will get set back to its default value (as specified in the Control Panel).

However, if you set the speed from a machine language program, the speed should remain the same for as long as that program maintains control.

LocalTalk PC Card: Using It With TOPS On A 640K IBM-PC/XT

Revised: 11/2/88
Security: Everyone

LocalTalk PC Card: Using It With TOPS On A 640K IBM-PC/XT

=====

This article last reviewed: 17 February 1987

When one PC has both an LocalTalk PC Card and a Centram TOPS card, problems (unrecognized cards and malfunctioning printing) that may occur might be isolated by testing each card separately for all functions and making sure both COM ports are free (the LocalTalk PC Card needs a free COM port).

You should also check the DMA settings of a file for the TOPS card, config.sys, and the switches for the cards for Centram TOPS and LocalTalk PC. The DMA settings must be compatible, e.g. config.sys with DMA=1, Centram TOPS card with switches set for DMA=1, and LocalTalk PC card with switches set for DMA=3.

Macintosh: Screen font character spacing

Revised: 5/10/89
Security: Everyone

Macintosh: Screen font character spacing

=====

The screen fonts distributed by Adobe have a slightly different character spacing than those distributed by Apple. Page 22 of the Adobe Type Library User's Manual points out:

"If you own an older Macintosh, not a Macintosh Plus, and are concerned about character spacing, avoid using the Bold and Italic selections from the Style menus of your application. Instead, install the bold, italic, and bold italic screen fonts available in your typeface package and select these fonts from your application's pull down menu when you need to change styles. You will then get more accurate spacing when printing documents."

The manual goes on to say:

"If you own a Macintosh Plus, you can install only the Plain font and still get correct character spacing. For display clarity, however, you may want to install the Other fonts."

If you are using a Macintosh with the 128K ROM's, only the Plain font needs to be installed. Just remember to use a Font/DA Mover of version 3.1 or later so the FOND resource is correctly installed.

Apple IIGS: ProDOS/8

Revised: 2/18/87
Security: Everyone

Apple IIGS: ProDOS/8

=====

To support the old Apple II mode on the Apple IIGS, system disks have P8, or ProDOS/8, as it is a version of ProDOS 1.1.1 made especially for Apple IIGS, although ProDOS/8 works on an Apple IIe or Apple IIc.

ProDOS/8 handles the following Apple IIGS capabilities, features and operating modes:

- ProDOS/8 accepts system calls from applications running in 8-bit mode only.
- ProDOS/8 accepts system calls from the lowest 64K of memory only.
- ProDOS/8 uses a simple global page bit map.
- ProDOS/8 maintains a section of memory, which can be accessed directly, that contains system global variables such as date and time, system level, and I/O buffer addresses.
- ProDOS/8 reads the Apple IIGS clock rather than the ThunderClock.

On the Apple IIGS, ProDOS and ProDOS/16 are designed to run in tandem, as a package. ProDOS/8 is provided to maintain compatibility with ProDOS v1.1.1. In normal situations, you need not be concerned with which operating system is functioning; ProDOS/8 is automatically loaded if you run an application designed to run under ProDOS 1.1.1 or versions earlier.

AppleWorks: Creating database documents from text with tabs

Revised: 2/18/87
Security: Everyone

AppleWorks: Creating database documents from text with tabs

=====

Some database programs export text files that have fields separated by tabs and records by carriage returns. AppleWorks imports a database file from a text file when all fields and records are separated by carriage returns. To convert the tabbed export format to the format AppleWorks imports, you must use a word processing application or a programming language, such as BASIC or Pascal, whether or not you have to transfer the data from the Macintosh.

Using a word processing application, open the document and change the tabs to carriage returns with a replace command. Most applications have special codes for the tab and carriage return, such as ^t and ^p in MicroSoft Word. Save the changes as a text file, which AppleWorks should accept.

For using a programming language, take this example in Applesoft BASIC under ProDOS.

```
10 ONERR GOTO 130
20 O$="<OLD FILE NAME>"
30 N$="<NEW FILE NAME>"
40 D$=CHR$(4)
50 PRINT D$"OPEN"O$
60 PRINT D$"OPEN"N$
70 PRINT D$"READ"O$
80 GET A$
90 PRINT D$"WRITE"N$
100 IF A$=CHR$(9) THEN A$=CHR$(13)
110 PRINT A$;
120 GOTO 70
130 PRINT D$"CLOSE"
140 END
```

This program should be saved, along with the exported text file, to a ProDOS disk; save the program with a name such as "TAB2CR". After substituting appropriate names in lines 20 and 30, run the program. AppleWorks should accept the output file.

Here is a MacPascal program that could convert the export file of a Macintosh

application such as MacWorks.

```
program Convert;
type
  text = file of char;

var
  infile, outfile : text;
  c : char;

begin
  {an example pathname could be 'HD:MS Works:ExportFile'}
  open(infile, 'export file pathname');
  open(outfile, 'AppleWorks format file pathname');
  while not (eof(infile)) do
    begin
      read(infile, c);
      if ord(c) = 9 then
        begin
          c := chr(13);
        end;
      write(c);    {echo to screen}
      write(outfile, c);
    end;
  close(infile);
  close(outfile);
end.
```

Substitute appropriate names for "export file pathname" and "AppleWorks format file pathname". After transferring the output file to the Apple II (with MS Works or MacTerminal), save the captured file as a text file. AppleWorks should accept the captured file.

Apple IIGS: ProDOS/16 version 1

Revised: 2/18/87
Security: Everyone

Apple IIGS: ProDOS/16 version 1

=====

With the Apple IIGS, Apple introduced an operating system for the IIGS, ProDOS/16, as ProDOS/16 version 1. ProDOS/16 version 1 was intended to implement the same call structure and many of the other features of ProDOS/16 in its final version.

Functioning as a shell around ProDOS/8 (the GS version of ProDOS 1.1.1), ProDOS/16 v1 has a user interface layer that mimics the external appearance and system call structure in its final version, but the actual operating system beneath the shell is ProDOS. Therefore, ProDOS/16 v1 is essentially restricted to functions that are available under ProDOS. Those parts of the final version that will involve fundamental revisions or extensions to ProDOS/8 are not available in ProDOS/16 v1. However, under ProDOS/16 v1, you will be able to:

- make ProDOS/16 system calls from anywhere in memory, using ProDOS/16 parameter blocks located anywhere in memory.
- make I/O data transfers to or from anywhere in memory.
- allow limited use of named devices in the VOLUME and GET_DEV_NUM calls. With ProDOS/8, you can only refer to a device by its volume name or its slot and drive number.
- support up to eight system prefixes; ProDOS/8 supports only one.

Modems, PhoneNETs and Key Switch Telephones (20Feb87)

Revised: 5/25/89
Security: Everyone

Modems, PhoneNETs and Key Switch Telephones (20Feb87)

=====

Modems, PhoneNETs and Key Switch Telephones (20Feb87)

When a modem is connected through a PhoneNET AppleTalk Connector to a RJ11 wall jack, the modem can electrically short the PhoneNET signal lines (yellow & black wires). This tech note describes what's going on and how to configure the modem from shorting the PhoneNET signal lines.

Many modems have a switch, jumper, or command that causes it to connect the yellow and black wires in a telephone jack. This feature is provided so that modems being used with a key switch multi-line office PBX will provide the correct signals to indicate that the modem line is in use and should not be picked-up at another phone.

The following commands, switches or jumpers will disable the modem from shorting the two wires normally used by PhoneNET connectors. Doing the opposite will cause the modem to indicate that the line is in use on multi-line key switch telephone systems.

```
Hayes Smartmodem 2400: issue commands AT&J0 or AT&J
Hayes Smartmodem 1200: set switch 7 UP
      Avatek 1200: only uses two wires
US Robotics Password 1200: pull up jumper J1
US Robotics Courier 2400: set switch 7 UP
      Apple Modem 300/1200: pull up jumper J1
      Apple Personal Modem: (made in USA) cannot be disabled, cut the yellow
                           and black wires in the telephone extension cable.
      Apple Personal Modem: (made in Hong Kong) only uses two wires
```

If you know how to configure modems that are not on this list, please let us know. Our AppleLink address is D0119. We intend to keep this list updated.

FullPaint and LaserPrint

=====

2/6/87

LaserPrint

LaserPrint is a utility by A2S bundled with FullPaint that enhances the resolution of FullPaint documents for printing on the LaserWriter.

Error While Printing

Clicking 'Print Final' generates either an 'Image mask' error or Offending Command 0' within Postscript in the LaserWriter.

Correction - Use PRINT DRAFT instead of PRINT FINAL

In effect, PRINT FINAL is trying is trying to convert (smooth) documents into 300 dpi that are already 150 dpi or 300 dpi.
PRINT FINAL is reserved for future versions of PostScript.
PRINT DRAFT bypasses smoothing routines.

+ Clearing the error

Turn off the LaserWriter and turn it back on

Printed Documents Not Smooth

Smoothing of documents for LaserPrint must be done by hand in Fat Bits within FullPaint.

+ Correction

- After splitting into 4 or 16, go back to FullPaint

- Smooth all the documents in Fat Bits

..TIL02146-FullPaint_and_LaserPrint_(TA36766).pdf

Setting ruler units to pixels and having Mouse Spot on screen makes it easier to retain shapes that go from one document to another.

- Return to LaserPrint
- Queue up documents as per the grid
- Click PRINT DRAFT

FullPaint Won't Boot?

=====

2/19/87

Sometimes an error message appears when the user tries to launch FullPaint saying that FullPaint requires 384K to run. This message may occur on both 512's and Plus'. Nothing is wrong with FullPaint or the Mac - the RAM cache needs to be turned off.

1. Turn RAM Cache off
 - RAM Caching in the Control Panel collides with the same address that FullPaint uses to open extra documents.
 - If Caching is on, FullPaint will NOT open under any circumstances.
- 1.1. Boot FullPaint
- 1.2. Choose CONTROL PANEL from the Apple menu
- 1.3. Click the OFF button for RAM Cache in lower right of window
- 1.4. Close the CONTROL PANEL
- 1.5. Click SHUTDOWN from the Special menu
- 1.6. Reboot

NOTE: Apple Computer, Inc. is not responsible for the contents of this article.

Macintosh: Feature Summaries for Finder 4.1, 5.4, and 5.5

=====

Article Created: 2 March 1987
Article Last Reviewed: 2 February 1991
Article Last Updated:

TOPIC -----

This article lists the features of Finder versions 4.1, 5.4, and 5.5.

DISCUSSION -----

Finder 4.1

These are the features added to Finder 4.1:

- Mini Finder
- Choose Printer Desk Accessory
- New Folder option
- Print Catalog
- Page Setup
- Shut Down
- About the Finder
- Up to 500 documents can be managed. (The previous limit was 130.)
- Icons can be moved, renamed, duplicated, or discarded from directories in any arrangement--view by icon, name, date, size, or kind.
- Directories are displayed in a text format (name, date, size or kind); a locked file displays a small padlock next to it.

- If the Finder encounters an error and can't reconstruct folders exactly, the top level of the folder hierarchy is always remembered (although the associated names are not).
- Open Dialog box matches user-entered characters.
- New combined Font/Desk Accessory Mover.

Finder 5.4

These are the features added to Finder 5.4:

- Trash can bulges when there's something in it.
- Two Get Info windows go side-by-side.
- Network Support:
 - Network files and volumes supported
 - Get privilege
 - Allows setting and viewing of access privileges
 - Shows folder names, location, user name, privileges, owner, group
 - Folder visual appearance indicates folder status.
- Option-drag operation copies an icon instead of moving it.
- Clean Up options: Clean Up Window, Clean Up Desktop, Clean Up Selection(s).
- Shutdown menu item initiates "housecleaning" on system, files, and desktop.
- Restart reboots the system.
- Control Panel accepts additional resources; Chooser 3.0 supports Zones.
- Size options added to RAM Cache.
- TeachText: Communicates undocumented changes; also a simple word processor.
- Startup Manager (SE and II only) Control Panel selection of any hard disk as Startup Device. Floppy insertion overrides startup selection.

Finder 5.5

These are the features added to Finder 5.5:

- Adjustment of window size from a larger screen when a window opens on a smaller screen.
- Resource errors less likely to cause a large desktop file.

- Dialogs and alerts centered on larger screens.
- Comments in the "Get Info" box copied properly when a file is duplicated.
- When boot disk is ejected, more icons (including small icons) are read into RAM, reducing the number of disk swaps required when changing disks.

ProDOS: Limited to 32 megabyte access on HD40SC and HD80SC

=====

This article last reviewed: 2 March 1987

A limitation of ProDOS prevents the Apple II from accessing more than 32 megabytes of storage space on an Apple Hard Disk 40SC or Apple Hard Disk 80SC. Those drives can be connected to an Apple II with an Apple II SCSI card.

SCSI Hard Disk Drives: Interleave Information (11/94)

Article Created: 2 March 1987
Article Reviewed/Updated: 09 November 1994

TOPIC -----

This article pertains to the interleave of Apple external SCSI hard drives of all sizes.

DISCUSSION -----

To initilaize a SCSI hard disk drive you want to use on a Macintosh:

1. Always use Apple HD SC Setup.
2. Always initialize from the type of Macintosh the drive will be connected to. For example, if you wish to connect a Apple HD40 SC to a Macintosh Plus, initialize that hard disk with a Macintosh Plus.

If you want more than one type of Macintosh to access the SCSI hard disk, always initialize it from the slowest system for the best average performance. You must do this because, with Apple HD SC Setup, different types of Macintosh computers require a SCSI hard disk with a different interleave.

Computer	Interleave	relative speed
Macintosh II and later	1:1	fast
Macintosh SE	2:1	medium
Macintosh Plus	3:1	slow
Apple II	3:1	slow

Interleave is the ratio of consecutive sectors a CPU can read from or write to. This means that a Macintosh II is fast enough to read from or write to every consecutive sector, a Macintosh SE can only read every other sector, and the Macintosh Plus is only fast enough to read one in every three sectors. An Apple

II also has an interleave of 3:1. The Apple II can support a 3:1 interleave because the SCSI card has a 8K RAM buffer enabling it to buffer data until the CPU is ready for it.

Delays occur when you connect a "slower" Macintosh to a hard disk initialized on a "faster" Macintosh. For example, a hard disk intialized from a Macintosh II has more data on every consecutive sector than a Macintosh Plus can consecutively read, necessitating a full revolution of the platter before the Macintosh Plus can access the sectors it knows it missed. There's a delay of the revolution of only one or two sectors when a "fast" Macintosh accesses a hard disk intialized from a "slower" Macintosh.

For the change in interleave ratio between the Macintosh Plus and the Macintosh SE, there are three reasons: improved performance, hardware handshaking, and changes in SCSI firmware. First, the Macintosh SE performs more quickly, even though it uses the Macintosh Plus' 68000 processor running at the same speed. The Macintosh SE has a change in hardware design that allows the video circuitry 1 long word access to the RAM for every 3 made by the processor, as opposed to the 1 video access for every 1 made by the processor on previous Macintoshes. Next, hardware handshaking was implemented, allowing cleaner and faster communication between the Macintosh SE and the drive. Finally, the SCSI firmware was cleaned up and optimized for the SE. Previous bugs and patches caused the SCSI driver to not perform as quickly as it should.

Macintosh SE: SCSI ID Number for Internal Hard Disk

Revised: 8/7/92
Security: Everyone

Macintosh SE: SCSI ID Number for Internal Hard Disk

=====

Article Created: 2 March 1987
Article Last Reviewed: 7 August 1992
Article Last Updated:

TOPIC -----

What is the SCSI (Small Computer Systems Interface) ID number for the optional internal 20MB SCSI hard disk?

DISCUSSION -----

The SCSI ID number is 0 for the optional internal 20MB SCSI hard disk available in the Macintosh SE. The CPU uses ID number 7, so additional SCSI devices connected to the Macintosh SE may use ID numbers 1 through 6. You must be able to set numbers 1 through 6 on any more SCSI devices you connect to a Macintosh SE with the optional 20MB SCSI internal hard disk. The internal hard disk's ID number, set in firmware, can't be changed.

Apple Tape Backup 40SC: Description (Discontinued) (9/93)

Revised: 12/1/93
Security: Everyone

Apple Tape Backup 40SC: Description (Discontinued) (9/93)

Article Created: 2 March 1987
Article Reviewed/Updated: 27 September 1993

TOPIC -----

The Apple Tape Backup 40SC, a SCSI block-type device for Macintosh computers with a SCSI port, provides data storage on removable 40MB magnetic tape cartridges. The unit contains all of the electrical and mechanical subsystems required to support a 1/4-inch tape drive and provide an intelligent SCSI port.

DISCUSSION -----

The tape backup unit uses the Group Code Recording (GCR) method on DC 2000 tapes. Each tape lasts for approximately 5,000 passes.

The Apple Tape Backup 40SC application allows you to backup data by volume or by file to your Apple Tape Backup 40SC unit. If you wish to backup by file, you have the additional option to backup files specifically (at any one HFS level) or incrementally since the last volume backup or last file backup.

When you restore by volume, be sure to restore to a hard disk of the same capacity. Restore by Volume completely replaces the directory of the hard disk. Therefore, if you are restoring a volume that has the capacity of 20MB onto a 40MB hard disk, that 40MB hard disk will only have a storage capacity of 20MB until you reinitialize it.

The Tape Backup 40SC backs up hard disks that use the HFS file system: all Apple hard disks and most hard disks made by other manufacturers.

IMPORTANT NOTE: The bundled software included with the Tape Backup 40SC is Tape Backup 40SC 2.0.1. Tape Backup 40SC 2.0.1 is INCOMPATIBLE with System 7 and greater. Apple recommends using third party backup software with the Tape Backup 40SC. Two third party applications which work with the Tape Backup 40SC are Retrospect/Retrospect Remote from Dantz Development Corp. and FastBack Plus from Fifth Generation Systems.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Apple Tape Backup 40SC: Cleaning guidelines

Revised: 5/4/88
Security: Everyone

Apple Tape Backup 40SC: Cleaning guidelines

=====

This article last reviewed: 2 March 1987

Your Apple Tape Backup 40SC unit requires very little maintenance. To clean the outside of the tape back up unit, just wipe it with a soft, damp cloth. To remove stains or dirt, add a drop of liquid detergent to the cloth and wipe the surface of the tape backup device.

It's time to clean the tape recording head when its surface looks dull (you can check this with a flashlight) or when it takes longer than normal to restore files or a volume from the tape backup unit. While similar to the heads on a hard disk, the ferrite-ceramic head of the tape unit may be cleaned as the heads are cleaned on a audio tape player or VCR. To remove debris and materials rubbed off from the tape surface, clean the head with a cotton swab soaked in isopropyl alcohol.

Caution: Never clean the head with a head cleaner that contains active or abrasive ingredients.

Macintosh II, IIx, IIfx: Power On and Power Off

=====

Article Created: 2 March 1987
Article Last Reviewed: 21 July 1992
Article Last Updated: 24 July 1992

TOPIC -----

Is there any difference between turning on my Macintosh II by using the Power On key on the keyboard or by pressing the button in back? What about powering off? Should I always do a Shut Down or can I just hit the button in back?

DISCUSSION -----

The Macintosh II, Macintosh IIx, and Macintosh IIfx computers do not have a "hard" power on and power off switch. There are two ways to turn on the computer: you can use the keyboard's Power On key or the power button next to the sound jack on the back panel of the computer.

Pushing the Power On key or the power button sends a request to the logic board to begin the startup sequence. Either way may be used; they are equivalent.

To power off the Macintosh II, IIx or IIfx, use the Shut Down command from the Finder. Choosing Shut Down permits the computer to close files that are open, update the directory on each disk, and power off the system.

Alternatively, you may press the power button on the back panel of the Macintosh. Doing so will power off the system immediately and any work that wasn't saved will be lost. Do not remove AC power from the system unless neither Shut Down nor the power button produce results. Removing power is likely to result in lost or damaged files because there isn't enough time for the computer to update disk information.

To restart the computer with a different boot disk or to cause the computer to recognize newly installed devices, you may wish to reboot the

Macintosh by choosing Restart from the Special Finder menu. The Macintosh will save file information as needed, power off the system, and immediately startup the system again.

Macintosh 128K ROMs: RAM cache

Revised: 9/17/87
Security: Everyone

Macintosh 128K ROMs: RAM cache

Macintosh computers with 128K ROMs include a Control Panel feature, RAM cache, through which the user can select the cache memory size.

To reduce the time the program uses for accessing a disk, RAM cache acts as a special RAM buffer between applications and disk drives. Blocks of data are read from disk into program memory and RAM cache. The application can flush from program memory certain data that the program needs later on. At that time, the program submits a request for the data from blocks on disk. If the blocks are still in RAM cache, the data can go from the RAM cache blocks to the application heap, saving the significantly greater time needed for disk access.

Of course, the RAM cache will eventually run out of space as the number of blocks of data read from disk increases. When this happens, new blocks overwrite the blocks of data used least recently, keeping frequently used sections of code in RAM cache to speed up operation of the system.

The RAM cache is capable of tracking 36 different files and may occupy from 32K to 768K of memory. A RAM cache of moderate size will not only increase speed within an application but will also cause applications to be launched from and return to the Finder more quickly.

The optimum RAM cache size depends on (and the use of RAM cache is largely dictated by) how memory and disk segments of code are juggled by one or more of the applications in use. Rarely are applications larger than 300K on disk, so a RAM cache of a slightly smaller size should be sufficient - say 256K. If you are using a very large program, it might be of some benefit to increase the size of the cache to 384K. However, if the cache is much larger than that, the document and program segments in use will only have available the restricted memory that begins to degrade performance.

While applications accessing a LaserWriter increase the need for disk access, there is only a small benefit to be had in increasing the size of the cache in this situation. Most applications will continue to operate very efficiently with a RAM cache of 256K.

It is possible to set the size of the RAM cache so high that the program cannot operate in the remaining space. MacWrite 4.5, for example, must have a minimum of 144K of memory to run and print to the LaserWriter. Don't set the RAM cache so high that less than 144K remains for the program.

The AppleLink article "Switcher: Memory Configurations for LaserWriter printing" includes a table that lists the preferred memory size needed by applications under Switcher. This information can provide a guideline for safe RAM cache sizes. Note that many of the programs will take advantage of more memory if it is available. If RAM cache is set high enough to cut into that capability, the cache will not necessarily improve overall performance.

Remember also that active desk accessories require dedicated memory. Some combinations of applications and desk accessories will occupy so much memory that the size of the RAM cache must be severely limited.

Apple Tape Backup 40SC: Specifications (Discontinued)

=====

Article Created: 6 March 1987

Following are the specifications for the Apple Tape Backup 40SC (part # M2640):

I. GENERAL SPECIFICATIONS

A. Storage Media

1. Type: 0.25-inch magnetic tape cartridge (DC 2000)
2. Length: 205 ft (62.5 meters)
3. Width: 0.25 in (6.35 mm)
4. Lifespan: 5,000 passes

B. Data Capacity

1. Total capacity: 38.5 MB
2. Encoding method: GCR (Group Code Recording)
3. Flux density: 12,500 ftpi
4. Bit density: 10,000 bpi (GCR)
5. Block size: 8192 bytes (8320 w/ 128 bytes of system data appended)
6. Number of tracks: 24 serpentine
7. Track width: 8 mils (.020 mm) write
5 mils (.0125 mm) read
10 mils (.025 mm) spacing

C. Speed and Timing

1. Tape speed: 60 ips R/W; 90 ips search/rewind
2. Drive data transfer rate: 600 Kb/s noninterleaved (uncorrected raw); 400 Kb/s noninterleaved (fully corrected)
3. SCSI data transfer rate:
 - avg. for continuous tape motion: 21.3 Kb/s corrected, noninterleaved
 - maximum burst rate: 500 Kb/s
4. Rewind time: 27 seconds, end-to-end (nominal)

5. Start/Stop time: 150 ms (nominal)
6. R/W head position time: 250 ms track-to-track

II. MECHANICAL SPECIFICATIONS

A. Dimensions

1. Height: 3.07 in (78 mm)
2. Width: 9.7 in (246 mm)
3. Depth: 10.5 in (266 mm)
4. Weight: 7.3 lb (3.3 Kg)

B. Temperature

1. Operating: 5 to 45 deg C (cartridge limited)
2. Shipping/Storage: - 40 to 65 deg C (hardware only)

C. Humidity

1. Operating: 20 to 80% (noncondensing)

D. Altitude

1. Operating: tested to 15,000 ft
2. Non-Operating: tested to 50,000 ft

III. ELECTRICAL SPECIFICATIONS

A. Input power

1. Line voltage: 85 to 270 VAC, 47 to 64 Hz
2. Power dissipation: 15W

B. Data interface: Two 50-pin SCSI ports

Hard Disk 40SC and Hard Disk 80SC: Specs (Discontinued 5/93)

=====

This article last reviewed: 29 March 1988

Following are the specifications for the Apple Hard Disk 40MB (part number M2644) and the Apple Hard Disk 80MB (part number M2688):

I. Capacity	HD 40SC	HD 80SC
A. Data capacity: (with HD Setup v1.5)	39,333K (formatted)	76,869K (formatted)
B. Disk diameter:	5 1/4"	5 1/4"
C. Data Surfaces:	4	6
D. Heads per surface:	1	1
E. Bytes per block:	512	512
F. Logical allocation block size:	1,024	1,536
G. Total disk blocks:	78,246	156,370
H. Sectors per track:	32	32

II. Characteristics

A. Avg. seek time:	30 msec	30 msec
B. Transfer rate:	up to 1.25MB	up to 1.25MB
C. Rotational speed:	3,662 rpm	3,662 rpm
D. Startup time:	13 sec	13 sec
E. Spin-down time:	18 sec	18 sec

III. Electric Requirements

A. Line voltage:	85 to 270 V AC	85 to 270 V AC
B. Frequency	47 to 64 Hz	47 to 64 Hz
C. Max. power:	60 watts	60 watts

IV. Environment Requirements

A. Operating temp:	50 to 104 deg F (10 to 40 deg C)	50 to 104 deg F (10 to 40 deg C)
B. Storage temp:	32 to 133 deg F (0 to 50 deg C)	32 to 133 deg F (0 to 50 deg C)
C. Relative humidity:	20 to 80% (noncondensing)	20 to 80% (noncondensing)
D. Altitude:	1000 to 10000 ft. (304 to 3048 m)	1000 to 10000 ft (304 to 3,048 m)

V. Size and Weight

A. Height:	3.1 in (78.5 mm)	3.1 in (78.5 mm)
B. Width:	9.7 in (24.6mm)	9.7 in (24.6mm)
C. Depth:	10.5 in (266 mm)	10.5 in (266 mm)
D. Weight:	9 lbs (4 Kg)	9 lbs (4 Kg)

VI. Interface: SCSI, 50-pin interface

Macintosh SE: Specifications (Discontinued 10/90)

Article Created: 16 September 1987
Article Last Reviewed: 6 August 1992

TOPIC -----

Following are the specifications for the Macintosh SE (2 floppies) and the Macintosh SE hard disk 20MB and 40MB (1 floppy, one 20 or 40 megabyte hard disk).

DISCUSSION -----

PROCESSOR

-MC68000, 32-bit internal architecture, 7.8336 MHz clock frequency

MEMORY

-256K ROM, 1 MB RAM (expandable to 4MB), 256 bytes of user-settable parameter memory

DISKS

- Capacity: 800K on double-sided 3.5-inch disks; 20MB (20.2 actual) or 40MB (42.1 actual) on optional 3-1/2" hard disk
- Bytes per block (20MB or 40MB hard disk): 512
- Total disk blocks:
 - 20MB hard disk: 39,360
 - 40MB hard disk: 82,150
- Avg. access time:
 - 20MB hard disk: 89 msec
 - floppy: 36 msec
- Avg. seek time:
 - 20MB hard disk: 65 msec
 - 40MB hard disk: 30 msec
- Transfer rate, max.:
 - 20MB hard disk: 1.25MB per second
 - 40MB hard disk: 1.25MB per second
 - floppy: 500K-bits per second

- Shock limit:
20MB hard disk: 40 G's
- Noise level:
20MB hard disk: 42 decibels-measured at seated operating distance

SCREEN

- 9-inch diagonal, 512-pixel by 342-pixel high-resolution bit-mapped display

INTERFACES

- Two Apple DeskTop Bus connectors
- Two RS-232/RS-422 serial ports
- SCSI interface
- External disk port
- Sound port for external audio
- 96-pin expansion connector (CPU bus connector)

SOUND

- 4-voice sound with 8-bit digital-analog conversion using 22 KHz sample rate

KEYBOARD

- Apple Keyboard (or Apple Extended Keyboard)

MOUSE

- Mechanical tracking, optical shaft encoding 90 pulses per inch (3.54 pulses per mm) of travel

CLOCK/CALENDAR

- CMOS custom chip with 7-year lithium battery

FAN

- 0 CFM Cross Flow

ELECTRICAL SPECIFICATIONS

- Input line voltage: 120/240 Volts AC, RMS
- Frequency: 47 to 63 Hz
- Power: 100 Watts maximum

SIZE AND WEIGHT

	Weight	Height	Width	Depth
Main Unit	17-22 lbs* 7.7-9.5 kg*	13.6 in 345 mm	9.69 in 244 mm	10.9 in 276 mm
Apple Keyboard	2 lbs 4 oz 1.0 kg	1.75 in 44.5 mm	16.5 in 418.3 mm	5.6 in 142 mm
Mouse	6 oz .17 kg	1.1 in 27.9 mm	2.1 in 53.3 mm	3.8 in 96.5 mm

* Weight varies depending on optional installed hard disk or second

3.5-inch drive.

ENVIRONMENTAL REQUIREMENTS

- Operating temperature: 50 deg F to 104 deg F (10 deg C to 40 deg C)
- Storage temperature: -40 deg F to 116.6 deg F
(-40 deg C to +47 deg C)
- Relative humidity: 5% to 95% (noncondensing)
- Altitude: 0 to 10,000 ft (0 to 3048 m)

AppleColor High-Resolution RGB: Degauss adjustments

Revised: 8/31/87
Security: Everyone

AppleColor High-Resolution RGB: Degauss adjustments

=====

The Degauss switch corrects small patches of color distortion that can occur on the screen. You should press the Degauss switch if, for example, you notice that a small area in an all-red field of the screen seems to be slightly off color, say, with blue. This situation is more likely if you've left the monitor on for a long time or if you moved the monitor while the power was on.

The switch is located just below the On-Off button on the back panel. Pressing the Degauss switch makes the screen flicker for a few seconds as the monitor corrects the colors in your display. When the image steadies, the colors should be correct.

LaserWriter Driver 3.3: Enhancements and fixes

Revised: 3/9/87
Security: Everyone

LaserWriter Driver 3.3: Enhancements and fixes

=====

LaserWriter Version 3.3 and LaserPrep Version 3.3 are on the disks for the Macintosh System Tools Version 1.0 and Utility Version 1.0 that ship with the Macintosh SE. Outlined below are some of the differences, enhancements and problem fixes, between these LaserWriter drivers and the older driver, 3.1, and earlier. Not listed are fixes to several obscure, minor, and cosmetic problems.

- A. The driver resets (software power-cycle) the LaserWriter if it was initialized with an incompatible driver version.
- B. There's a fix to a problem encountered in all applications, most notably in Microsoft Excel: bytes were randomly written in memory, causing some programs to crash when printing.
- C. Bitmap printing has been completely changed to improve appearance and performance.
 - 1. There's an added routine, similar to smoothing, which pre-stretches bitmaps to the required dimensions before imaging; this allows bitmaps to print much faster.
 - 2. Clipping problems in bitmaps are gone.
 - 3. Random garbage in stretched bitmaps is gone.
 - 4. "Stitching" between bands of adjacent bitmaps has been greatly improved to eliminate hairline gaps.
- D. Bitmap fonts have been changed for greater speed. Bitmap fonts above 36 points now download and print correctly and print faster in a higher quality.
- E. There's a fix to a long-standing bug in the orientation of rotated QuickDraw patterns on various types of printers.
- F. Fonts on PostScript printers are no longer pre-coordinated at printer

initialization time but only as they are needed. This frees room for downloading other fonts and doesn't require spoolers to know anything about font coordination.

- G. Because they required more than 30 seconds to generate data for the printer, some applications were aborted for insufficient activity on the network. This timeout has been extended to 5 minutes.
- H. If a PostScript error occurs, a print error is now generated by the driver to tell the application to stop printing. The error message stops the application from having to generate any more document data which the driver would ignore anyway.
- I. Font substitution is now disabled in all cases where fractional pixel widths have been enabled. Disabling font substitution fixes a bug encountered by applications that use the fractional pixel width mode, such as WriteNow, Word 3.0, PageMaker 2.0, and MicroSoft Works.

Previously, single-font paragraphs could appear printed with different lines in the non-substituted form as well as the substituted font.

- J. Font downloading now occurs whenever it might improve output or if the font might not be available on the printer. This solves the problem on some 3rd party spoolers which sometimes did not have the font available.
- K. Some minor problems with dialog boxes were fixed along with some cosmetic changes made to dialog boxes and alert windows.
- L. Bitmaps one pixel wide can be printed.
- M. Zero width characters are now printed correctly. This fixes a bug where some characters in fonts such as Music and other symbols could not be printed.
- N. Cover sheets now default to print in Helvetica instead of Courier.
- O. Document names sometimes defaulted to the last document printed. Now, if a document name is not known, "unknown" appears in the dialog box.
- P. There's a fix to a bug in printing circles and ovals where some of these objects, when rendered extremely narrow or flat, had gaps at the beginning and end joints.
- Q. Sometimes the driver had difficulty printing when the amount of memory available in the Macintosh was low. This caused unrepeatable crashes with strange result codes. Though this problem cannot be detected or eliminated in all cases, the fix has made the situation significantly more robust and reliable.

-- If enough memory is not available for printing, the driver will try to reduce its memory requirements enough to print. If it cannot, it will abort the printing altogether. It will print slowly or not at all, but at least it won't crash.

- R. A problem in the QuickDraw comment to include PostScript in a handle has been fixed so that the QuickDraw comment now works correctly.
- S. If the printer is reinitializing, the driver will now wait until the printer is available.
- T. Another alert for spoolers was added. If the remote printer is actually a spooler rather than a printer, initialization of the printer is not permitted.

Apple Desktop Bus: Maximum Number of Devices

Revised: 7/26/89
Security: Everyone

Apple Desktop Bus: Maximum Number of Devices

=====

This article last reviewed: 6 May 1989

The Apple Desktop Bus, or ADB, is available on the Apple IIGS, Macintosh SE and Macintosh II for connecting keyboards, mice and other input devices to the system. The Apple Desktop Bus protocol will accomodate up to 16 devices.

ADB devices are typically daisy-chainged together. Some devices may contain enough internal resistance to limit the number of devices you can connect. For instance, a maximum of 4 Apple Keyboards or Apple Extended Keyboards plus 1 mouse may be daisy-chained together before increases in DC resistance result in drops below TTY levels. It is possible to connect 5 Apple IIGS ADB keyboards and a mouse together before resistance increases to where input via some devices will be "lost". Look out for other ADB devices that may have similar traits.

If input isn't reaching the CPU, break the chain into two chains (supported by 2 ADB ports on the Macintosh SE and Macintosh II).

An Apple IIGS has only one ADB port, so if input isn't reaching the CPU, power off the GS, connect the particular ADB input device or devices you wish to use, then connect a limited number of other ADB devices, power up, and try again. Alternatively, "Y" connectors could help create additional chains and reduce the number of devices on any one of the those chains.

Apple Tape Backup 40SC: Priority number

Revised: 5/4/88
Security: Everyone

Apple Tape Backup 40SC: Priority number

=====

This article last reviewed: 9 March 1987

SCSI device users have available eight priority numbers, 0 through 7. The Macintosh is always assigned number 7. An internal hard disk is always assigned 0. That leaves 1 through 6 to assign to your tape backup unit or 0 thru 6, if you don't have an internal SCSI hard disk.

Though the manual recommends you use priority 1 for the Tape Backup 40SC and connect it to the last SCSI device in the chain, you can use any of the other priority numbers if they are not already used. You may place the tape backup unit anywhere else in the SCSI bus as long as it is properly terminated. For a more complete description on how to connect SCSI devices, refer to the manual, "The Apple SCSI Cable System."

Apple PC 5.25 Drive: Not Compatible with MS/DOS Computers

=====

Article Created: 9 March 1987

12/15/92 - RETITLED
• To clarify the article

TOPIC -----

Can you attach an Apple PC 5.25 Drive to a MS/DOS computer?

DISCUSSION -----

No, you cannot attach an Apple PC 5.25 Drive to a MS/DOS computer.

First, MS/DOS computers do not supply power to an external floppy drive. The Apple PC 5.25 drive requires the computer to supply power to it, since it does not have its own power source.

Also, the Apple PC 5.25 Drive requires there be a control line for the signal "disk insert". MS/DOS computers put a different signal on this control line.

Macintosh II PC 5.25 Floppy Disk Controller Card: Description

Revised: 5/11/89
Security: Everyone

Macintosh II PC 5.25 Floppy Disk Controller Card: Description

=====

The Floppy Controller card is capable of interfacing up to 4 drives, although the cable limits the actual connection of only one drive. User installable with instructions in the Apple PC 5.25 " Drive Users Guide, the card interfaces the Apple PC 5.25" Drive to the Macintosh II through any of the slots on the Macintosh II motherboard.

Through software, you can select two recording formats: IBM 3740 Single Density Format and IBM System 34 Double Density Format. The controller allows for multi-sector transfer capability; up to 3 sectors can be read/written in one read/write operation.

Full IBM PC/AT data format compatibility allows the IBM PC/AT to read disks formatted and written by the Macintosh II. The Macintosh II is also able to read data files created on the IBM PC/AT, but the controller does not give the Macintosh II the ability to run programs written for the IBM PC/AT.

Key Components

Address/Data Bus Transceivers: These 74LS640's buffer the internal address/data bus of the controller from the Nubus address/data bus.

AddressCounters: These 74LS169 counters latch the RAM/ROM address from the Nubus during RAM/ROM reads or writes and count down the RAM address during DMA transfers to or from the disk.

RAM: This is the 2048 x 8 sector buffer RAM. Data to be transferred to or from the disk is placed here by the CPU before such transfers are initiated.

ROM: This is the Nubus configuration ROM. The Nubus slot manager accesses this ROM on power-up to determine the controller's type and modes of access.

Slot Address Decoder PAL: The Pal20L10 determines if the controller's slot address is selected. It uses the signal START* and address decoding to compare if the upper nibble of the address is an x'F and if the address lines A[24-27]/D[0-3]* compare with the hard wired slot ID address.

State Machine PAL: This PAL20X10 generates the timing for programmed I/O and internal DMA transfers on the controller.

State Decoder PAL: The state number is decoded by this PAL to produce control signals needed by the various parts of the controller.

Control/Status Driver: The control driver places the signals ACK*, TMO* and TM1* on the Nubus at the end of a Nubus access of the controller. The status driver allows the signals, disk controller interrupt, internal operation pending, and disk in place to be read by the CPU.

NEC 765A Floppy Disk Controller IC: This LSI chip contains the circuitry necessary to interface to the Apple PC 5.25" Drive. Coupled with the companion NEC 9201 chip, it handles all operations with the drive including read and write data, formatting, seeking, sensing drive status, and recalibrating.

NEC 9201 Floppy Disk Interface IC: This chip provides drive and timing support to the NEC 765A IC. It contains write precompensation and phase-locked loop circuitry.

Disk Interface Driver: The disk interface driver buffers and provides current drive for several signals coming from and going to the disk. It also is used as a multiplexer for four signals: FLT/TRO, WP/TS, FR/STP, and LCT/DIR.

16 MHz Crystal Clock Oscillator: This oscillator provides a 16 MHz clock to the NEC 9201 for use in the drive interface.

Nubus Interface Logic

The controller interfaces to Nubus via several drivers and PAL's. The address/data bus is tied to four 74LS640 transceivers which invert each bit. Control signals such as START*, the slot identification bits ID[0-3]*, and the mode bits TM[0-1] are used to time data transfers to and from Nubus.

Status information is passed to Nubus along with the control signal ACK* by the status driver using Programmed I/O operations. DMA operations are controlled by the state machine and state machine decoder PAL's. All data transfer operations are initiated and controlled internally.

Connectors/Cables/Pinouts

Controller Card to Drive: A cable composed of a 37 pin male connector on one end and a 34 pin edge connector and 4 pin DC connector on the other. A 20 pin cable makes the interconnection. Pinouts for the 37 pin, 34 pin, and 4 pin connectors correspond to the pinouts of the Apple PC 5.25" Drive.

Power Requirements:

Operating Voltages:

Security: Everyone

Macintosh SE PC 5.25 Floppy Disk Controller Card: Description

=====

Article Created: 9 March 1987
Article Last Reviewed: 7 August 1992
Article Last Updated:

TOPIC -----

This article describes the Macintosh SE PC 5.25 Floppy Disk Controller Card.

DISCUSSION -----

The Floppy Controller card is capable of interfacing up to four drives though the cable limits actual connection of only one drive. Installed by the dealer, the card interfaces the Apple PC 5.25" Drive to the Macintosh SE through the bus expansion slot on the Macintosh SE logic board

Through software, you can select two recording formats: IBM 3740 Single Density Format and IBM System 34 Double Density Format. The controller allows for multi-track and multi-sector transfer capability, permitting the entire disk to be read/written in one read/write operation.

Full IBM PC/AT data format compatibility allows the IBM PC/AT to read disks formatted and written by the Macintosh SE. The Macintosh SE is also able to read data files created on the IBM PC/AT but does not give the Macintosh SE the ability to run programs written for the IBM PC/AT.

Key Components

Control PAL's: These three 20 pin PAL's provide the address decoding and timing control for the disk controller. All controlling firmware and sector buffering RAM exists in the Macintosh SE. The control registers are mapped into the Macintosh SE's address space from \$800000-\$8FFFFFF.

Data Bus Transceivers: These 74LS245 buffers provide multiplexing control and sufficient current drive to and from the controller onto the data bus.

During high byte transfers, data is placed on D8-15; during low byte transfers, the data goes on D0-7.

Status Driver: The status driver allows the signals disk controller interrupt and diskette change to be read by the Macintosh SE.

NEC 765A Floppy Disk Controller IC: This LSI chip contains the circuitry necessary to interface to the Apple PC 5.25" Drive. Coupled with the companion NEC 9201 chip, it handles all operations with the drive including read and write data, formatting, seeking, sensing drive status, and recalibrating.

NEC 9201 Floppy Disk Interface IC: This chip provides drive and timing support to the NEC 765A IC. It contains write precompensation and phase locked loop circuitry.

Disk Interface Driver: The disk interface driver buffers and provides current drive for several signals coming from and going to the disk. It also is used as a multiplexer for four signals: FLT/TRO, WP/TS, FR/STP, and LCT/DIR.

16 MHz Crystal Clock Oscillator: This oscillator provides a 16 MHz clock to the NEC 9201 for use in the drive interface.

AMD 9516 Dual Channel DMA Controller and DMA Control PAL: The 9516 DMA controller handles all DMA data transfer operations between the NEC 765A and the Macintosh SE memory.

DMA Address and Data Multiplexing Logic: The 9516 has a multiplexed address and data bus. The multiplexing logic is used to demultiplex this bus. The logic consists of two 74LS373's and two 74LS245's.

Interface Logic

The controller interfaces to the 68000 bus via several drivers and PAL's. The timing of the 68000 bus is followed by the controller whether in PIO or DMA transfers.

All control information is passed to the disk controller and all status information is transferred to the host using Programmed I/O transfers. All data information is transferred to or from the host using DMA transfers.

Back panel to Drive: A cable composed of a 37 pin male connector on one end and a 34 pin edge connector and 4 pin DC connector on the other. Pinouts for the 37 pin, 34 pin, and 4 pin connectors correspond to the pinouts of the Apple PC 5.25" Drive.

Power Requirements:

Operating Voltages:

+ 5V +/- 5%
+12V +/-10%

Maximum Ripple:

@ + 5V 50 mV peak to peak

@ +12V 100 mV peak to peak

Operating Current (Apple PC 5.25" Drive Attached)

@ + 5V 3.3A (max)/1.9A (typ)

@ +12V 0.9A (max)/0.25A (typ)

Macintosh II Managers: Changes From Macintosh Plus ROMs

Revised: 7/20/92
Security: Everyone

Macintosh II Managers: Changes From Macintosh Plus ROMs

=====

Article Created: 11 March 1987
Article Last Reviewed: 20 July 1992
Article Last Updated:

TOPIC -----

A number of existing managers in the Macintosh Plus ROM have been expanded for use in the Macintosh II. This article provides a short description of these managers and the changes.

DISCUSSION -----

Font Manager

Fonts in ROM now include Monaco 9, Geneva 9 and 12, as well as Chicago 12. There are also 4 and 8-bit versions of Chicago 12 and a 4-bit Geneva 9 font. No new data structures are defined within the Font Manager, but the `fontType` structure has been modified to support color fonts. It now includes a field that indicates the depth of the font.

Window Manager

A new data type, `CWindowRecord`, has the same structure and size as the old `WindowRecord`, except the field `port` is now defined as a `CGrafPort` rather than the old `GrafPort`. Two other new types related to `CWindowRecord` are `CWindowPtr` and `CWindowPeek`. Another new data structure, `AuxWinRec`, stores the necessary information for drawing windows in color. Its primary function is to hold the handle to the window's individual color table.

Control Manager

The Control Manager has been expanded to include color support with the definition of a new data structure, `AuxCtlRec`, and its corresponding resource type `cctb`. These structures define a color table associated with the control and determine the border color, fill color, and text color for

the control.

Menu Manager

The Menu Manager now uses scrollable menus instead of QuickDraw to display menu text. Scrollable menus means that scrolling is possible with an up or down arrow at the top or bottom of the menu. The Menu Manager now implements up to five levels of hierarchical menus

A new data structure, MbarProc, holds information pertaining to the menu bar. Menu items themselves have been disassociated from the menu bar definition to permit hierarchical menus to be handled more easily.

Color menus are implemented through the Menu Color Information Table. A distinct MCInfoRec may exist for the menu bar and for each menu title and item. Within each MCInfoRec, you find RGBColor information for the item in question and its background color.

TextEdit

A TextEdit record may now have style information associated with it. A handle to a TStyleRec structure can replace the TextEdit fields txFont and txFace. This style record holds an array of "runs", each of which may use a different text style (font, face, size, color, line height, and font ascent).

Style information can be passed from TextEdit to the application through a TextStyle record, which includes font, face, size, and color information. When the scrap is used to cut and paste style information, a new scrpSTElement type is used to transfer style and start character information.

Dialog Manager

Two new resource types, actb and ictb, add color and style information to alerts and dialogs, and dialog item lists. These resources are associated with a dialog or alert by assigning them the same resource ID as the parent ALRT or DITL.

International Utilities Package

The International Utilities Package has been extended to support the new Script Manager. It now includes multiple resources within a given script, and new date and time formatting options. International scripts with non-Roman sorting rules may specify the details via hooks in this package, so that the many diacritical forms of the same letter may be treated for sorting purposes as equals regardless of diacritical marks, accents, umlauts, circumflexes, etc., e.g. a umlauted can be equated with a accented.

File Manager

The Macintosh II File Manager can be used with an external file system

other than the traditional Macintosh code.

Print Manager

The Printing Manager has added one call to ROM: the print glue file (called PRLINK or PRSCREEN) has moved from the system file into the Macintosh II ROM.

Device Manager

The Device Manager has been modified to include support for NuBus cards, both as boot devices, and through the interrupt process.

The Device Manager gains control of the Macintosh II bootup process shortly after video and boot drivers have been initialized. If the Startup Device has been set to one of the NuBus slots, and the configuration ROM found there contains boot code, the Device Manager will pass control to that NuBus device. If the Macintosh II continues its boot process from a Macintosh disk, the Device Manager will search all NuBus slots, looking for device drivers in the configuration ROM of each NuBus device. Any that are found there are installed into the system heap and initialized for later use by an application.

The Device Manager is the software interface for tracking the interrupt queue, determining the priority level that is proper to address, and, if necessary, posting an error when the interrupt cannot be serviced.

SCSI Manager

The Macintosh II and Macintosh SE ROMs implement an SCSI "blind" transfer mode. The types of SCSI drives used in these computers may support hardware handshaking, when blind transfer mode will result in faster transfer rates.

AppleTalk Manager

The AppleTalk Manager supports several changes to its code to assist servers, workstations, and spoolers:

- The node number of the computer may be requested in the server range.
- Packets may be sent to one's own node, or through a client-specified socket.
- The Name Binding Protocol can now accept multiple active requests.
- An Echo Protocol and an AppleTalk Session Protocol have been added.
- An Extended Protocol Package (XPP) combines portions of the AppleTalk Session Protocol and AppleTalk Filing Protocol.

Vertical Retrace Manager

The Vertical Retrace Manager has been changed slightly to take into account the flexible video interface on the Macintosh II. Since certain tasks on the Macintosh depend on the vertical retrace interrupt that occurs on the Macintosh 60 times every second, the Macintosh II must continue to supply that signal. The Vertical Retrace Manager can attach tasks to that pseudo VBL signal.

Macintosh II: Color capabilities

Revised: 7/1/92
Security: Everyone

Macintosh II: Color capabilities

=====
Article Created: 11 March 1987
Article Last Reviewed: 30 June 1992
Article Last Updated:

TOPIC -----

The Macintosh II adds color capabilities to the Macintosh line of computers. Its implementation depends on the Toolbox calls available, and on the hardware installed in the system. This document describes the relationship between the hardware and firmware, and discusses color implementation in the Macintosh II Toolbox.

DISCUSSION -----

ABSOLUTE COLOR

Color QuickDraw, as defined in the Macintosh II ROMs, uses an absolute approach to determine color representation. A new data type, `RGBColor`, is defined to be a record containing three 16-bit integers, each of which represents an intensity value for one of the three additive primary colors: red, green, and blue.

type

```
    RGBColor = record
        red:integer;    {Red component}
        green:integer;  {Green component}
        blue:integer;   {Blue component}
    end;
```

Under Color QuickDraw, the application need not be concerned with the type of output device. The application specifies a color in `RGBColor` format, but the Color Manager then uses information from the device's driver to translate the `RGBColor` definition into the best available match on the output device. Some output devices may be limited to 8 or 16 colors; others use a lookup table to select from a wide range of possible display

colors. In any event, the Color Manager handles these details independently of Color QuickDraw or the application.

COLOR DEPTH

On the Macintosh II, the user can choose the depth to which the screen image should be displayed, up to the limits of the video hardware, by using the Control Panel desk accessory. This permits choosing a display consistent with the type of program. A word processing application may need only black and white, and a greater selection of colors (i.e., greater depth) would only slow down the application. On the other hand, drawing and charting applications benefit from the ability to use more colors, so the user might choose to use a greater pixel depth.

Pixel depth must be a power of 2. A display of 4 bits per pixel permits each pixel to choose from among 16 colors, while 8 bits per pixel allows a selection of 256 colors. Normally, the device implements these choices through a color lookup table controlled by the Color Manager.

THE PIXMAP

All drawing by Color QuickDraw is done in a pixel map, which is analogous to the bit map of old. New fields have been added to track the horizontal and vertical resolution in pixels per inch, the number of bits per pixel, and the handle to the pixel map's color table.

COLOR PATTERNS

Color QuickDraw includes color patterns. It provides an undefined limit to the size of the pattern, and a variable pattern depth. Although Color QuickDraw is capable of translating the depth of a pattern to the current screen display depth, this can be a time-consuming process, and should be avoided. As always, color patterns provide a method of dithering, which increases the number of perceived colors shown on the screen.

COLOR TRANSFER MODES

Color capabilities introduce new opportunities for transfer modes. Some previously defined transfer modes aren't useful when color display is used, so Color QuickDraw offers new ones:

- Replace with transparency
Permits overlay of pictures
- Additive
Adds red, green and blue components on the screen, resulting in a lighter screen image.
- Subtractive
Subtracts red, green and blue components on the screen, resulting in a darker screen image.
- Max and min

Compares the source and destination values, and chooses either the smaller or the larger. Used to smooth the edges of two objects displayed next to each other.

- Blend

Uses a formula to calculate a mix of the source and destination values of each component.

Macintosh II: NuBus capabilities

Revised: 7/21/92
Security: Everyone

Macintosh II: NuBus capabilities

=====
Article Created: 11 March 1987
Article Last Reviewed: 21 July 1992
Article Last Updated:

TOPIC -----

The Macintosh II includes six NuBus slots to provide expansion capabilities for the computer. These slots may be used for video output, processors and coprocessors, terminal devices, and serial and parallel devices, among other uses.

DISCUSSION -----

The logic board's 68020 communicates with each of the six synchronous NuBus slots through the memory management unit. A full 32-bit address/data transfer is available between each slot and the 68020. Each slot is identified to the microprocessor by four ID lines, which the 68020 uses to determine the source of the communication. Power, timing, acknowledge, and parity lines are also implemented. Apple has changed Texas Instruments' NuBus definition by adding an interrupt line from each slot, so that each card can generate an interrupt to the 68020.

The 32-bit address space (equating to 4G bytes) available for all NuBus slots is partitioned to provide space for each slot. First, the top 256M of address space is divided into 16 "slots." This allows each physical slot to "own" 16M, which is referred to as its Slot Space. Each NuBus slot is also allocated 256M of "SuperSlot Space" from the portion of memory remaining in the 4G of address space.

Each NuBus card should contain a configuration ROM mapped to the top of its Slot Space to provide information for the Macintosh II operating system at startup time. The Macintosh II looks at the ROM to determine the type of card, how it is to be accessed, and slot resource data.

Pre-defined card categories include display, network, terminal emulator,

serial, parallel, intelligent bus, and human input devices. Each category is further defined by a type indicator. For example, the network category is subdivided into AppleTalk, EtherNet, Token Ring and so on. NuBus device drivers can then locate any appropriate card by checking these bytes in configuration ROM on each card.

NuBus cards can be designed to be "masters" of the bus, or as slaves only. A master card must be able to initiate bus transfers of 8, 16, or 32 bits, and must be able to arbitrate requests for bus mastership. It may include the ability to lock the bus from access by other NuBus devices for a specified period of time. A slave card responds to requests, but can only send a "non-master request." It need not support the full 32-bit transfer.

Card manufacturers may choose to implement a NuBus card with only a 24-bit logical address mode to provide compatibility with existing Macintosh products. This mode is supported by using only address lines 0 through 23, and is called "24-bit aliasing."

Macintosh II: Sound capabilities (3/94)

=====

Article Created: 11 March 1987
Article Reviewed/Updated: 9 March 1994

TOPIC -----

This article provides an overview of the sound capabilities introduced by the Macintosh II.

DISCUSSION -----

The Macintosh II extends the sound capabilities of the Macintosh Plus by implementing the software Sound Driver in an Apple Sound Chip and the Sound Manager in the Macintosh II Toolbox. The hardware permits sound to be played asynchronously of other Macintosh II operation, while the software is flexible enough to support additional sound hardware through a NuBus slot or the external stereo sound port.

Macintosh II Sound Hardware

Sound is produced on the Macintosh II by a custom digital sound chip (the Apple Sound Chip), two Sony sound chips, and an internal speaker or through the external sound jack. The Apple Sound Chip generates an audio/stereo signal, which is then filtered and buffered by the Sony sound chips. The Apple Sound Chip also contains a 1024 byte FIFO buffer to accept sound values. This permits the Macintosh II to more frequently operate asynchronously of sound generation, and to provide stereo capabilities.

Sound may be played through the 2 1/4" internal speaker, or through the external stereo mini-jack. The jack will not drive a speaker directly, but can use a Walkman-style headphone.

The Sound Manager

There are four standard synthesizers defined within the Macintosh II Sound Manager. Each of the synthesizers is controlled by commands passed to them via a channel, or queue, of commands. A common set of commands is available to each of

the synthesizers, with extensions as appropriate for each individual driver. Sound Manager routines can direct a synthesizer to the queue that holds the sound commands, play the channel, set up new channels, etc.

Each channel is interpreted according to the rules supplied by the called synthesizer, and data is passed through the Apple Sound Chip's two FIFO buffers to the internal speaker or to the external sound jack. Since the internal speaker is monophonic, the Sound Chip will combine all four channels (if used) into one voice for the speaker. When the external sound jack is used, two voices are kept separate, with two channels used in each. Either sound output device may be used asynchronously of other Macintosh II operation while the Sound Chip feeds channel information to the speaker in use.

The note synthesizer allows a simple melody to be played. It permits monophonic sound only, and should be used to play simple sounds, such as SysBeep.

Either monophonic or polyphonic sound is possible using the wave table synthesizer. It may be used to produce voice sound by triggering the synthesizer at non-regular intervals.

The MIDI (Musical Instrument Digital Interface) synthesizer provides a way to play music on an external device via a MIDI synthesizer through the serial ports of the Macintosh II. Since the type of sound depends largely on the type and sophistication of the external equipment, the limits of its capabilities are largely hardware defined.

Pre-recorded sounds may be played back through the sampled sound synthesizer. The pitch, rate, and amplitude may be varied as the sound sample is played. The synthesizer has the ability to alternately play two buffers to provide uninterrupted sound as long as the buffers are refilled by the application when a channel of sound is completed.

If a programmer wishes to expand upon the synthesizers provided in the Macintosh II ROM, he may do so by defining a synthesizer or sound resource. The Sound Manager can call the new resources to play existing channels, using the rules defined by the new synthesizer. This feature permits developers the flexibility to develop external sound hardware via NuBus slots, while using the Sound Manager to provide a consistent interface for sound software.

Macintosh II, IIfx, & IIfx: Startup sequence

=====

Article Created: 11 March 1987
Article Last Reviewed: 21 July 1992
Article Last Updated: 24 July 1992

TOPIC -----

What happens exactly when I turn on my Macintosh II by pressing the Power On key on the keyboard?

DISCUSSION -----

The Macintosh II, IIfx, and IIfx are turned on via the Power On key, which is located above the numeric row of keys on Apple Desktop Bus Extended keyboards.

When this key is pressed on an ADB keyboard connected to one of these Macintosh computers, it grounds pin 2 (the Power On signal) on the Apple Desktop Bus port. This line is physically connected through a resistor to the lithium batteries found on the logic board.

The batteries charge a capacitor which toggles the power supply to turn on (assuming AC power is present). Power-up continues with a system check before control is passed to the Startup Manager in the ROM.

After power is supplied to the system, the Versatile Interface Adapters and IWM (SWIM in the IIfx's case) are initialized, memory is tested, and RAM and ROM are mapped to permanent locations. A video card is located, and video is initialized. The Start Manager is then ready to check for a startup device.

If a bootable disk is present in an internal floppy drive, that disk is used to start the system. If both floppy drives are empty, parameter RAM is checked for the location of the designated startup device, and that device is searched for system startup blocks. Should that be unsuccessful, SCSI devices are checked followed by a search for intelligent NuBus cards.

Once a device with boot block information has been found, the blocks are read and the code is executed. At that point, control passes from the Start Manager to the start application code.

Security: Everyone

The Macintosh II and SE: Differences that aren't apparent

=====

Article Created: 11 March 1987
Article Last Reviewed: 26 June 1992
Article Last Updated:

TOPIC -----

There are a number of obvious differences between the Macintosh SE and the Macintosh II. The situations below describe differences that are not apparent.

DISCUSSION -----

Number of Supported Floppy Drives

The Macintosh SE has an external drive port, but the Macintosh II does not. If two floppies are installed internally, the Macintosh SE can support as many as three floppy drives. The Macintosh II can support no more than two floppy drives, and cannot support an Apple HD20 or external floppy drive.

SCSI Drive Interleave Scheme

The ROMs of the Macintosh SE and Macintosh II have different SCSI disk interleaving schemes. Although disks are interchangeable, they will work most efficiently on the system on which they were initialized. The Macintosh SE uses a 2-to-1 interleaving scheme, while the Macintosh II uses 1-to-1 interleaving.

Therefore, a SCSI disk initialized on a Macintosh SE and moved to a Macintosh II will not transfer data as quickly as a Macintosh II SCSI drive, since the Macintosh II will be forced to wait for every other block of data, rather than using them in sequence.

If a Macintosh II SCSI drive is taken to a Macintosh SE, the speed difference will be even more apparent. The Macintosh II drive will have

blocks allocated in sequence on each track. But the Macintosh SE will not be able to accept the data that quickly, so the drive must make almost a full rotation before the second block again passes under the head, and the information can be read from the drive.

Security: Everyone

Comparing the Macintosh Plus and Macintosh II

=====

Article Created: 11 March 1987
Article Last Reviewed: 8 June 1992
Article Last Updated: 11 May 1989

TOPIC -----

What are the major differences between the Macintosh Plus and the Macintosh II?

DISCUSSION -----

Several notable differences exist between Macintosh Plus and Macintosh II functions. Some of these items are listed below:

External Drive Port

There is no external drive port on the Macintosh II. An Apple HD20, 400K external drive, or 800K external drive cannot be connected to the Macintosh II.

Battery Location

The battery is no longer located within the power supply. Instead, it is soldered onto the logic board, and can only be replaced by a level 1 technician.

Serial Port Pinouts

While both the Macintosh Plus and Macintosh II use mini-DIN-8 connectors for serial ports, one signal has been changed on the Macintosh II and the Macintosh SE. Pin 7, which is not used on the Macintosh Plus, is now a general purpose input pin. It is connected to the serial communication chip's data carrier detect line on the Macintosh II. Pin 7 on the modem port may also be used as a SYNC line, since it is connected to the clock line from the VIA.

SCSI Terminator Power

The Macintosh Plus does not provide terminator power on its SCSI port. The Macintosh II has added this signal to pin 25 of the external SCSI connector.

Keyboard and Mice Connections

Keyboards, mice, and other input devices on the Macintosh II are now connected through an Apple Desktop Bus port. The DB-9 connector used for this purpose on the Macintosh Plus is no longer available.

SCSI Interleaving Schemes

The ROMs of the Macintosh Plus and Macintosh II have different SCSI disk interleaving schemes. Although disks can be used interchangeably, they will work most efficiently on the system on which they were initialized. The Macintosh Plus uses a 3-to-1 interleaving scheme, while the Macintosh II uses 1-to-1 interleaving.

Therefore, a SCSI disk initialized on a Macintosh Plus and moved to a Macintosh II will not transfer data as quickly as a Macintosh II SCSI drive, since the Macintosh II will be forced to wait for every third block of data, rather than using them in sequence.

If a Macintosh II SCSI drive is taken to a Macintosh Plus, the speed difference will be even more apparent. The Macintosh II drive will have blocks allocated in sequence on each track. But the Macintosh Plus will not be able to accept the data that quickly, so the drive must make almost a full rotation before the second block again passes under the head, and the information can be read from the drive.

Power On/Off Switch

The Macintosh II has no hard power on/off switch. Instead, the Power On key on the Apple Desktop Bus keyboard initiates a request for power-on to the Macintosh II. This key is not a power-off key; power-off is provided through software via the Shut Down command in the Finder.

Macintosh II: New Managers

Revised: 7/20/92
Security: Everyone

Macintosh II: New Managers

=====

Article Created: 11 March 1987
Article Last Reviewed: 20 July 1992
Article Last Updated:

TOPIC -----

The Macintosh II has a number of new managers in ROM and in system software that have no analog on the Macintosh Plus. This article provides a brief description of each of these new managers.

DISCUSSION -----

Color Manager

The Color Manager controls the task of translating an application's color requests to a color capable of being displayed by the current hardware. It keeps information about the display in a device record with information concerning the type of search mechanism to be used for color matching and inverting, as well as a handle to its pixel map.

The Color Manager sets up an initial color table for each GrafDevice with default values, which correspond to the colors defined by the original QuickDraw. Color Manager procedures can also manipulate individual colors in a color table, so that an application can "fine tune" the mapping of the program's color description to the color displayed on the screen device.

Color QuickDraw

Color QuickDraw includes the same types of procedures and calls found in "old" QuickDraw, but it has expanded to support color on the Macintosh II in GrafPorts, pixel maps, icons, polygons, and cursors.

Color cursors and color icons are implemented through two new data structures, CCrsr and CIcon. Each type of polygon has a new fill procedure

to permit color drawing. A typical definition is:

```
Procedure FillCRect(r: rect; ppat: PixPatHandle);
```

Script Manager

The Script Manager is used by TextEdit, or may be called by an application directly, to provide the means for an application to be written independently of the language (or script) in use.

The Script Manager provides a consistent interface to Roman and non-Roman alphabets, those that use right-to-left and left-to-right progression, and alphabets with other than the "standard" 26 Roman characters.

Start Manager

The Start Manager controls the bootup process on the Macintosh II. Once power is supplied to the Macintosh II and control has been transferred to the ROM, the Startup Manager determines which microprocessor is present, initializes ROM Managers, and checks for initialization code within the declaration ROM of all NuBus cards. The Start Manager then attempts to locate an appropriate startup device, and executes its boot blocks.

Apple Desktop Bus Manager

The Apple Desktop Bus Manager controls those devices on the Apple Desktop Bus (typically a keyboard and mouse). The ADB Manager supports calls to and from ADB devices and supplies information about keys pressed, mouse clicks, etc., to other managers.

Slot Manager

The Slot Manager in the Macintosh II provides the means for the on-board ROM and logic to communicate with cards in the NuBus slots. The Slot Manager interprets the information supplied by NuBus cards, and arbitrates requests for bus mastership.

The Slot Manager checks each NuBus card's declaration ROM and sets up a Slot Parameter Block data structure, which can be accessed by other Slot Manager routines. Applications, or more likely, device drivers, may then request the Slot Manager to read data of varying lengths from a card in a NuBus slot.

Sound Manager

The Macintosh II Sound Manager replaces the 64K and 128K ROM Sound Driver. All previous data structures, routines, and synthesizers are supported in the Sound Manager, and new routines have been added to take advantage of the new Apple Sound Chip on the Macintosh II logic board, including four standard synthesizers:

- Note synthesizer
- Wave table synthesizer

- M.I.D.I synthesizer
- Sampled sound synthesizer

A programmer may expand upon these synthesizers by defining a synthesizer or sound resource. The Sound Manager can call the new resources to play existing channels, using the rules defined by the new synthesizer.

Deferred Task Manager

Because the Macintosh II supports interrupts through all six NuBus slots, a manager is needed to handle the interrupts in an orderly fashion. The Deferred Task Manager determines the appropriate time to service each of the requested interrupts, depending on the level of interrupt requested and other activity occurring within the Macintosh II.

Shutdown Manager

The Shutdown Manager is designed to provide a consistent way for the Macintosh to be turned off or to be rebooted from the Finder as well as from within an application. It allows the system to perform some housekeeping prior to turning off or rebooting. Custom ShutDown procedures may be installed and removed through routines available in the ShutDown Manager.

Operating System Utilities

Routines in the Operating System Utilities provide the ability to switch between 24-bit address mode, required for compatibility with existing Macintosh applications, and 32-bit address mode allowing access to the full 32-bit addressing capability of the MC68020 and NuBus slots.

NuBus: Glossary of terms

=====

Article Created: 11 March 1987
Article Last Reviewed: 21 July 1992
Article Last Updated:

TOPIC -----

This article contains a glossary of NuBus terms.

DISCUSSION -----

Following are common NuBus terms:

- NuBus

A synchronous bus defined by Texas Instruments. It operates on a 10 MHz clock, with a full 32-bit data and address transfer. Apple's implementation of NuBus does not include parity checks, but does add interrupt lines to each of the Macintosh II NuBus slots.

- Bus master

At a given time, the bus device that initiates a transaction. Also, a device with the ability to initiate a NuBus transaction by asserting the START* line.

- Configuration ROM (also declaration ROM)

A 1M portion of the minor slot space. Each card must include information within this space to identify itself to the Macintosh II at startup. Items included here are the type of card, the location of its driver, if present, the byte lanes it will use to communicate with other NuBus devices, and slot resource data.

- Major slot space (also SuperSlot Space)

A portion of memory in the address range \$9000 0000 to \$F000 0000. By convention, each card may use 256M in this space. A card in slot 1 would use from \$9000 0000 to \$9FFF FFFF, a card in slot 2 would use addresses \$A000 0000 to \$AFF FFFF, and so on. This address assignment is not enforced; cards may use more than 256M of space, as long as addressing conflicts do not occur between slots.

- Minor slot space (also Slot Space)

A portion of memory within the NuBus address space from \$F000 0000 to \$FFFF FFFF. Each slot is assigned 16M of memory beginning at \$Fs00 0000, where s is the card's physical slot location.

- Slave device

At a given time, a device that responds to a transaction. Also, a device that cannot initiate a NuBus transaction or arbitrate requests for bus mastership.

Macintosh II NuBus Slots: Pinouts and signal descriptions

=====
Article Created: 11 March 1987
Article Last Reviewed: 21 July 1992
Article Last Updated:

TOPIC -----

This article contains the pinouts for Macintosh II NuBus slots.

DISCUSSION -----

All NuBus slots in the Macintosh II have the same pinouts:

Pin	Row A	Row B	Row C
---	-----	-----	-----
1	-12V	-12V	RESET
2	GND	GND	GND
3	SPV	GND	+5V
4	SP	+5V	+5V
5	TM1	+5V	TM0
6	AD1	+5V	AD0
7	AD3	+5V	AD2
8	AD5	GND	AD4
9	AD7	GND	AD6
10	AD9	GND	AD8
11	AD11	GND	AD10
12	AD13	GND	AD12
13	AD15	GND	AD14
14	AD17	GND	AD16
15	AD19	GND	AD18
16	AD21	GND	AD20
17	AD23	GND	AD22
18	AD25	GND	AD24
19	AD27	GND	AD26
20	AD29	GND	AD28
21	AD31	GND	AD30

22	GND	GND	GND
23	GND	GND	PFD
24	ARB1	-5.2V	ARB0
25	ARB3	-5.2V	ARB2
26	ID1	-5.2V	ID0
27	ID3	-5.2V	ID2
28	ACK	+5V	START
29	+5V	+5V	+5V
30	RQST	GND	+5V
31	NMRQ	GND	GND
32	+12V	+12V	CLK

Signal descriptions for these lines are:

- +5V
Power to slot; 2 amps per slot maximum continuous.
- +12V
Power to slot; 0.25 amps per slot maximum continuous.
- -12V
Power to slot; 0.1 amps per slot maximum continuous.
- -5.2V
Unused
- GND
Power return for +5V, +12V, and -12V
- RESET
Open collector signal; card should use to reset circuitry.
- SPV
Slot Parity Valid; asserted if card provides parity. Never asserted under Apple NuBus.
- SP
Slot Parity; odd parity of AD0-AD3 if SPV asserted.
- TM0 - TM1
Transaction modifiers.
- AD<31:0>
Address/Data bits 31 to 0.
- PFW
Power Fail Warning given 2ms before AC power is lost.
- ARB<3:0>
Arbitration bits 3 to 0; arbitrates system mastership.
- ID<3:0>
Geographical address 3 to 0; hard-coded to slot.

- START
Asserted to indicate an address on AD lines.
- ACK
Acknowledge of START cycle.
- RQST
Request; asserted to request bus mastership.
- NMRQ
Non-master request; used to signal an interrupt.
- CLK Clock. Asymmetrical 10MHz clock; synchronous transactions on NuBus.

Macintosh: External SCSI Port Pinouts (7/94)

Revised: 7/18/94
Security: Everyone

Macintosh: External SCSI Port Pinouts (7/94)

Article Created: 18 September 1987
Article Reviewed/Updated: 18 July 1994

TOPIC -----

What are the pinouts for the 25-pin SCSI port on the rear of most desktop Macintosh computers?

DISCUSSION -----

All Macintosh computers with the external 25-pin SCSI port have the pinouts listed below. Note that the Macintosh II and Macintosh SE do supply terminator power on pin 25, unlike the SCSI port on the Macintosh Plus.

Pin	Signal name	Signal description
1	REQ/	Request
2	MSG/	Message
3	I/O/	Input/Output
4	RST/	SCSI bus reset
5	ACK/	Acknowledge
6	BSY/	Busy
7	GND	Signal ground
8	DB0/	Data bit 0
9	GND	Signal ground
10	DB3/	Data bit 3

11	DB5/	Data bit 5
12	DB6/	Data bit 6
13	DB7/	Data bit 7
14	GND	Signal ground
15	C/D/	Common/Data
16	GND	Signal ground
17	ATN/	Attention
18	GND	Signal ground
19	SEL/	Select
20	DBP/	Data parity
21	DB1/	Data bit 1
22	DB2/	Data bit 2
23	DB4/	Data bit 4
24	GND	Signal ground
25	TPWR	Terminator power

IMPORTANT: Because the SCSI port is a DB-25 connector, it looks like a RS-232 port. It is NOT a RS-232 port. Do NOT plug an RS-232 device into the SCSI port. Doing so will most likely damage the SCSI chip on the logic board.

Macintosh II: ROM Features Different From Mac Plus (9/95)

Revised: 9/1/95
Security: Everyone

Macintosh II: ROM Features Different From Mac Plus (9/95)

=====

Article Created: 11 March 1987
Article Review/Updated: 1 September 1995

TOPIC -----

The Macintosh II ROM features were greatly extended from those found in the Macintosh Plus. A number of new managers were added to the ROM, and most existing managers were modified to support the new hardware capabilities of the Macintosh II.

The modifications most frequently introduced involved color support - QuickDraw, menus, dialog boxes, and TextEdit are among those items that were extended with color features. The Nubus slots were also a prime candidate for causing additions and changes. The Macintosh II introduced a Slot Manager, an Operating System Utilities Manager, and the Deferred Task Manager to support Apple's Nubus implementation.

Other managers were rewritten to remove previous limitations: the Macintosh II was an open machine, so the ROM designers made every effort to permit developers the freedom to design products for the Macintosh II without being concerned with ROM limitations.

DISCUSSION -----

The following managers are new to the Macintosh II ROM:

Begin_Table

Color Manager
Color QuickDraw
Scrip Manager
Start Manager
Apple Desktop Bus Manager
Slot Manager
Sound Manager
Deferred Task Manager

Shutdown Manager
Operating System Utilities

End_Table

These managers underwent significant changes from the Macintosh Plus ROM:

Begin_Table

Font Manager
Window Manager
Control Manager
Menu Manager
TextEdit
Dialog Manager
International Utilities Package
File Manager
Printer Manager
Device Manager
SCSI Manager
AppleTalk Manager
Vertical Retrace Manager

End_Table

In all cases, previously defined calls, data types, and resources are recognized by the Macintosh II ROM, but extensions to those capabilities were added in the revised managers.

HD-20SC: What You'll Need to Format It With an Apple II

=====

This article last reviewed: 19 January 1988

To format an HD-20SC drive using an Apple II, it's usually best to use System Disk 3.0. System Utilities 2.1.1 can be used for this purpose only with some versions of the Apple IIe, as described below.

- Apple IIGS: requires System Disk 3.0. (System Utilities 2.1.1 won't do it.)
- Unenhanced Apple IIe: is not compatible with System Disk 3.0. (Use System Utilities 2.1.1.)
- Apple IIe (Platinum) with Rev C logic board: use System Disk 3.0 to format an HD-20SC. (System Utilities 2.1.1 won't do it.)
- Apple IIe (Platinum) with Rev E logic board: it's advisable to use System Disk 3.0. System Utilities 2.1.1 can be used, but you'll see flashing garbage on the screen that will make it look like the system has crashed.

AppleShare Workstation: Switch Launching

Revised: 10/18/88
Security: Everyone

AppleShare Workstation: Switch Launching

=====

This article last reviewed: 13 March 1987

While using an AppleShare workstation, you can switch launch to an old Finder (even one that is not "Appleshare aware") and still be connected to AppleShare.

If you do so, however, you will not get the new icons that signify access privileges to various folders; the only icon you will see is the normal white one. However, even though this signifies the ability to see files within that folder on an AppleShare volume, you will not have any more ability to view the contents of folders than you had under Finder 5.4. This is because access control checking is done in the server, not by the Finder; you get the icon that says you have access to a folder because that's the only folder icon that the older Finders have.

Switch launching loads the System and Finder of a non-startup disk into the Macintosh. Launching is double-clicking on an icon, and switch launching switches the Finder when you:

- launch an application on a non-startup disk that has an old Finder that switches automatically,
- hold down the option key when you launch the application, providing the Always Switch Launch bit is set in the application, or
- hold down the option and command keys when you launch the non-startup Finder.

Bar Codes and Readers

Revised: 9/29/90
Security: Everyone

Bar Codes and Readers

=====

This article last reviewed: 30 August 1990

TOPIC -----

I am thinking of using bar codes for some special inventory uses, but don't know which one to choose. Can you help?

DISCUSSION -----

There are industry standards for bar coding. Virtually every manufacturer of computers and peripherals for instance has standardized on the Code 3-of-9 (Code 39) format. They have done so for a number of reasons. While most bar code formats are numeric only, Code 39 is an alphanumeric bar code consisting of all uppercase alphas A through Z, numerals 0 through 9, and a half dozen or so punctuation marks. Code 39 is a variable-length bar code. Anywhere from a single character to 30 or more characters (space and scanning hardware permitting) can be in a bar code.

Code 39 is in the public domain, which means that programmers can freely accommodate printing Code 39 in their programs.

UPC is clearly the most visible bar code in the US, and it is also the most useless to 98% of the population. It is a special-purpose bar code that is used by manufacturers whose products will be sold in retail stores with scanning equipment. This pretty much limits UPC to supermarkets and some record stores. UPC is hard to print and there is no reason to do so. Most currently available bar code scanners "autodiscriminate" which means they automatically decode several different bar code formats.

Instant Pascal 1.5 Update: Erratum

Revised: 3/13/87
Security: Everyone

Instant Pascal 1.5 Update: Erratum

=====

There is a technical error in the Instant Pascal 1.5 Update document. The 1.5 Update document says on page 2 that:

312K or 356 blocks of contiguous memory is required to install Instand Pascal on a hard disk or on a RAM card.

This is incorrect.

The statement should be amended to:

A utility program, IP.Custom has been added so that you can install Instant Pascal on a hard disk or RAM card with at least 512 blocks (256K) of contiguous memory. Instant Pascal does not run on the Applied Engineering RAMDisk because the RAMDisk does not contain 512 contiguous blocks of memory (independent of the size of the RAMDisk).

AppleWorks: Number Of Copies Printable At One Time

Revised: 2/8/88
Security: Everyone

AppleWorks: Number Of Copies Printable At One Time

=====

This article last reviewed: 16 March 1987

In AppleWorks, you have many different printing options. One of these options is the "How many copies?" you want to print. The default setting for this option is 1 copy. You can print up to 9 copies from AppleWorks at one time. If you attempt to enter a number larger than 9, the speaker beeps.

If you are in the Word Processor, you can have the computer print more than one copy of the document at a time.

1. Move the cursor to the bottom of the document.
2. Place a NEW PAGE option after the last line.
3. Enter Open-Apple-C, Copy to the Clipboard, and enter Open-Apple-1. This selects all of the document. Press RETURN and a copy of the document will be placed in the clipboard.
4. You can now copy additional documents at the end of the existing report. Use the Open-Apple-C, "Copy FROM the Clipboard", and a copy of the document will be added to the end of the file.

You can now print up to 18 copies of the document. Depending on the size of the document, you can Open-Apple-Copy more copies of the document and print even larger quantities of the document.

4	BGACK/	Ground	A1
3	BR/	Ground	FC0
2	VMA/	Ground	FC1
1	VPA/	Ground	FC2

Here is a description of the signals in the system expansion slot.

Signal	Description
FC0-FC2	68000 Function Code lines
A1-A23	68000 Address lines
E	68000 E Clock
C8M	Microprocessor clock = 7.8336 MHz = C16M divided by 2.
C16M	Gate Array Clock = 15.6672 MHz
HALT/	68000 Halt. Wired directly to RESET/
IPL0/-IPL2/	68000 Interrupt Priority Level lines
BERR/	68000 Bus Error. Generated by gate array due to SCSI access timeout.
Ext.DTK/	Pull low to put the gate array generated DTACK/ into a high-impedance state. The expansion board is then responsible for generating the DTACK/signal (as an output to the microprocessor, through the DTACK/signal line).
VPA/	68000 Valid Peripheral Address. Supplied to 68000. For Macintosh SE, VPA space is \$E0 0000 to \$FF FFFF.
VMA/	68000 Valid Memory Address
BR/	68000 Bus Request
BGACK/	68000 Bus Grant Acknowledge
BG/	68000 Bus Grant
DTACK/	68000 Data Transfer Acknowledge. Inserts wait states until data bus is available. Normally supplied by the gate array. Gate array generation of DTACK/ can be suppressed (put into a high-impedance state) by pulling the EXT.DTACK/line low; this allows DTACK/ to be externally generated by an add-on device. DTACK/ is not supplied for accesses to VPA space, is held off to separate 2 successive accesses to the SCC and is held off during RAM access by video.
R/W/	68000 Read/Write

LDS/	68000 Lower Data Strobe
UDS/	68000 Upper Data Strobe
AS/	68000 Address Strobe
PMCYC/	Processor-Memory Cycle. Used to synchronize with the gate array for RAM accesses. PMCYC/ is low when RAM is available for microporcessor accesses and is high during video aceses. PMCYC/ is always high during SO.
RESET/	68000 Reset. Wired directly to HALT/.
D0-D15	68000 Data Bus

Additional information may be found in the the Motorola 68000 manual.

Apple IIGS: Setting and using a RAM disk

=====

This article last reviewed: 17 March 1987

To set and use the RAM disk, follow these steps:

1. Go into the control panel (CTRL-Open Apple-ESC) and set the RAM disk at a convenient size, say a minimum and maximum of 800K, the size of the Apple 3.5 drive.
2. Reset the Apple IIGS with a warm boot: CTRL-Open Apple-RESET.
3. Load system utilities.
 - a. List volumes. The RAM disk should be recognized in slot 5, drive 2, as "/RAM".
 - b. Format the RAM disk.
 - c. Copy to the RAM disk whichever files you wish, such as AppleWorks 2.0.

Now if you want to use the RAM disk as the system volume:

1. Make sure that you have loaded ProDOS onto the RAM disk.
2. Go into the control panel desk accessory. To set the startup, use the up or down arrow keys to choose the menus Slots and Start up slots, and then use the right or left arrow keys to choose the RAM disk.
3. Warm boot the Apple IIGS by pressing CTRL-Open Apple-RESET. Whatever is in the RAM disk should start up.

To get the RAM back:

1. Set the RAM disk to 0K.

2. Turn off the power on the IIGS. A reset will not reset the memory.

BEWARE: Save the data periodically in case of crash or power failure!

Composite Color Monitors: Why They Display 80-Column Text Poorly

Revised: 5/25/89
Security: Everyone

Composite Color Monitors: Why They Display 80-Column Text Poorly

=====

This article last reviewed: 21 January 1988

80-column text is usually difficult to read when displayed on a composite color monitor.

The major problem is the bandwidth of the monitor: to properly display 40-column monochrome information requires a minimum of 4 MHz bandwidth. Television receivers are near the bottom end at 4.5 MHz. Monochrome monitors are usually specified with a bandwidth of 12 MHz, for sharpness with an 80-column display. If color information is displayed too, the minimum bandwidth doubles, to 24 MHz. The problem with many televisions that have direct video inputs is that they are still limited to the television bandwidth of 4.5 MHz, which is inadequate for displaying 80-column information.

Macintosh 68000 Development System Becomes Consulair

=====

The product Macintosh 68000 Development System, MDS, is obsoleted as of March 2, 1987. After this date, MDS will be available as the "Consulair 68000 Development System" from:

Consulair Corporation
140 Campo Drive
Portola Valley, CA 94025

The MDS upgrade also ended March 2, 1987.

Macintosh Pascal: Doing Screen Dumps

Revised: 4/2/87
Security: Everyone

Macintosh Pascal: Doing Screen Dumps

=====

To print a screen shot from Macintosh Pascal (versions 1.0, 1.1, 2.0, and 2.1):

- Select the ImageWriter or ImageWriter II from the Chooser. It may be connected to either the Printer or the Modem port. (The Modem port is available only in versions 2.0 and 2.1.)

- Type "Command-Shift-4" to print the current screen.

NOTES: --Command-4 does not print the current window.

- If you have a LaserWriter or an AppleTalk ImageWriter selected as the printer when you try to do a screen dump, Macintosh Pascal will simply "beep". If you wish to print a screen to an AppleTalk ImageWriter or LaserWriter, use Command-Shift-3 (to create a MacPaint file) and then print from MacPaint.

Pascal 1.3: Using it on a Hard Disk 20SC

Revised: 4/2/87
Security: Everyone

Pascal 1.3: Using it on a Hard Disk 20SC

=====

When using Apple Pascal 1.3 (as well as versions 1.0, 1.1, and 1.2) on an Apple II, you cannot use the Hard Disk 20SC as a volume: since Pascal stores the volume size as a signed integer, it cannot work with volumes larger than 32767 blocks. (The HD 20SC has 39165.) The Hard Disk 20SC can be formatted from Apple Pascal, but when you attempt to use the Pascal FILER to copy files to the drive, you get a "NO ROOM ON VOLUME" message. Furthermore, Apple Pascal only supports 77 files per directory, so even if you could use the Hard Disk 20SC, you would run out of directory space before you could even come close to running out of disk space.

The directory limitation applies to 5 meg and 10 meg ProFile drives as well. You can use a ProFile hard drive with Pascal 1.3, but you cannot "share" the drive with ProDos: you must dedicate the entire hard drive to a maximum of 77 Pascal files.

Apple Personal Modem: Making it Work with AppleLine

Revised: 7/26/89
Security: Everyone

Apple Personal Modem: Making it Work with AppleLine

=====

If you have no problems accessing an Apple Modem 300/1200 through AppleLine but cannot seem to access an Apple Personal Modem, the APM's auto-answer mode is most likely preventing it from answering.

The auto answer mode is one of the differences between the Apple Modem 300/1200 and the APM. With the Apple Modem 300/1200, the default for the S0 register is S0=1 (that is, "answer the phone on the first ring"). The default for the APM's S0 register, though, is S0=0 (that is, "do not answer any ring"). Try connecting a system to the APM and resetting the S0 register to S0=1. Then, without powering down the modem, connect it to the AppleLine. The modem will now be in auto answer mode, and, unless powered down or reset, it will answer incoming calls on the first ring.

Another possibility is that you are using the wrong cable. For the APM, you should be using a 590-0331 (the cable used for connecting an Apple Personal Modem to an Apple IIe with a Super Serial Card) along with the modem eliminator cable 590-0029.

Macintosh Internal Hard Drive: Problems When Using Other Drives

=====

Article Created: 19 July 1989
Article Last Reviewed: 7 August 1992
Article Last Updated:

TOPIC -----

When I hook up an external SCSI hard drive to my Macintosh SE, the internal drive crashes at bootup. What's going on?

DISCUSSION -----

When used with other external SCSI drives, a Macintosh SE or Macintosh II equipped with an internal SCSI drive may develop compatibility problems, such as the inability to boot up without crashing. This happens because:

- The Macintosh internal SCSI drive and the external hard drive have the same SCSI priority number.
- The external drive contains an older driver that will not work with the newer Macintoshes.

The first problem pertains only to those external SCSI drives that have the SCSI priority number set to 0 in their firmware, such as the AST 4000. Although AST drives are presently jumpered to have a priority number of 0, AST is replacing the jumper block on the 4000 with a dip switch, which will make changing the priority easier. The priority numbers in other AST and external Rodime drives are either set to a number other than 0 or can be changed easily. A customer who needs to change the priority number of a AST 4000 should contact AST for complete directions.

The workaround to the second problem is simply to update or reinitialize the driver using the Apple HD SC Setup.

SCSI Terminator: Description of the connections inside

Revised: 9/29/90
Security: Everyone

SCSI Terminator: Description of the connections inside

=====

This article last reviewed: 2 April 1987

This article describes the connections inside the SCSI terminator, Apple part number 590-0348.

Each of the pins listed below is connected straight through the connector (e.g., 1 to 1, 2 to 2, etc.). In addition, each of the signal pins is connected through a resistor network to terminator power.

An example follows:

Pin 26 (DB0) is connected to pin 26. It is also connected to pin 1 (DB0 GND, its corresponding ground) through a 330 ohm resistor and to a common line, which terminates in pin 38 (Terminator power), through a 220 ohm resistor. Similar connections occur for each signal pin.

Pin 38 (TERMPWR) is connected to the common line proceeding from the 220 ohm resistors. Pin 11 (DIFFSENS) is connected straight through only.

Here are the connections used in the SCSI terminator:

--Connect the following pins straight through to the same pin at the other end of the connector:

1 through 9,11,16,18 through 34,38,41,43 through 50

--Connect the first pin of each of the following pairs to a 330 ohm resistor, then to the second pin of the pair, then to a 220 ohm resistor, then to the terminator line.

1 -- 26
2 -- 27
3 -- 28
4 -- 29
5 -- 30

6 -- 31
7 -- 32
8 -- 33
9 -- 34
16 -- 41
18 -- 43
19 -- 44
20 -- 45
21 -- 46
22 -- 47
23 -- 48
24 -- 49
25 -- 50

--Connect pin 38 to the common terminator line.

HD-20: Erasing Information to Government Specs

=====

Article Created: 2 April 1987

Article Change History

08/27/92 - REVISED

- To provide information on "HD 20 Test" version 1.1, and how to use it to perform a low-level format of the hard drive that meets Government specs for erasing the disk.

TOPIC -----

I used my HD-20, non-SCSI hard drive, while working on a U.S. Government contract, which is now completed. I need to erase the information on the hard drive in accordance with Government specs, or the Government will confiscate my hard drive, so they can destroy it.

The Finder's Erase Disk option is not suitable for erasing sensitive Government information because it simply erases the disk's directory.

Do you have a utility that zeros all blocks, including those that were previously spared?

DISCUSSION -----

"HD 20 Test" version 1.1 has a data-destructive, low-level formatting feature that can be used for this.

The low-level formatting feature of "HD 20 Test" version 1.1 is hidden. To access it:

- 1) Launch the program.
- 2) When the main dialog appears, press "Command-D", and a new dialog

appears. This dialog displays what is actually happening during the diagnostic cycle. It also provides more detailed options.

- 3) Click the radio button marked "Dstrct" at the lower right of the dialog box to perform a data-destructive, low-level format on the drive (all zeros are written to every block).

Note

A 24-hour extended diagnostic test is also available with "HD 20 Test" version 1.1 as a hidden feature. Press "Command-E" when the main dialog appears to access this feature.

Apple IIGS: 6502 communications applications (1 of 2)

=====

Some assembly language programmers may want to convert 6502 communications software to use the IIGS logic boards to the full. To insure future compatibility when using the Apple IIGS serial ports through assembly language, you should use the built-in firmware calls. The firmware works very well, is very fast, and also provides you with a built-in interrupt handler and input/output buffers. All of these features can be managed through ROM calls.

More advanced use (bit and register handling) would require familiarity with the "Z8030/Z8530 Serial Communication Chip Technical Manual" from Zilog. Information there reveals that communications on the 8530 is much more complicated than that on the 6551; a straight conversion may not be that simple.

Zilog Inc.
210 Hacienda ave.
Campbell CA. 95008

Here are some examples of how you might use the serial ports with the built-in firmware. NOTE: all these examples use the Pascal interface in the ROM.

To initialize your programs and the port you might use something like this:

InitVector	equ	\$C20D	; pointer to the init routine in ROM
ReadVector	equ	\$C20E	; Pointer to the read char routine
WriteVector	equ	\$C20F	; pointer to the Write routine
StatVector	equ	\$C210	
ExtendVect	equ	\$C212	; Pointer to the extended interface routine
InitPort	equ	\$F8	; set up some area's for indirect jumps
ReadChar	equ	\$FA	; to be used in the program to make the
WriteChar	equ	\$FC	; calls to ROM
StatusCall	equ	\$FE	;
ExtendCall	equ	\$F6	; New vector for extended interface

```
InitPort      lda    InitVector    ; First set up your indirect pointers
              sta    InitPort

              ldy    #$C2          ; make sure to set the high byte
              sty    InitPort+1
              lda    ReadVector
              sta    ReadChar
              sty    ReadChar+1
              lda    WriteVector
              sta    WriteChar
              sty    WriteChar+1
              lda    StatVector
              sta    StatCall
              sty    StatCall+1
              lda    ExtendVect
              sta    ExtendCall
              sty    ExtendCall+1

              ldx    #$C2          ; Now make the init call to the ROM
              ldy    #$20          ; Always set up the X and Y Regs first
              jsr    (InitPort)    ; and indirect jump to the init routine
              cpx    #0            ; test for an error

Sending AppleWorks Word Processor Files to the Macintosh

Revised: 9/1/87
Security: Everyone

Sending AppleWorks Word Processor Files to the Macintosh

=====

By printing a text file through the printer port, you can send an AppleWorks word processor file to the Macintosh. You can make the text file by selecting the disk drive as the "Printer" in the "Specify Printer Information" section.

You may have some problems with the communications program you are using on the Macintosh. For instance, MacTerminal will ignore all characters past the 80th character if it does not receive a carriage return (in fact, this was the reason for the change in AppleWorks 2.0). Microsoft Works requires that you enter a "Capture Text" mode; otherwise, it will receive just one page of information.

AppleWorks 1.3 or earlier will print the file to a text file with carriage returns at the end of every paragraph. After it is in a text file, you can use a terminal program, such as Access II, to send the file over the modem line. If you do not have a communications program, then the following small BASIC program should suffice:

```
5  ONERR GOTO 90
7  SLOT = 1
10 D$ = CHR$(4)
15 F$ = "textfile" : REM You may use any file name.
17 PRINT D$;"PR#";SLOT
20 PRINT D$;"OPEN";F$
30 PRINT D$;"READ";F$
40 GET A$
60 PRINT A$;
80 GOTO 40
90 PRINT D$;"CLOSE"
95 PRINT D$;"PR#0"
100 END
```

AppleWorks 2.0 inserts a carriage return at the end of every line when printing to disk. However, the program below strips off the carriage returns if the following character is not a space or another carriage return.

```
10  ONERR GOTO 130
```

```
20  O$ = "oldfilename" : REM You may use any file name.
30  N$ = "newfilename" : REM You may use any file name.
40  D$ = CHR$(4)
50  PRINT D$;"OPEN";O$
60  PRINT D$;"OPEN";N$
70  PRINT D$;"READ";O$
80  GET A$
82  IF A$ <> CHR$(13) THEN 100
83  B$ = A$
84  GET A$
86  IF A$ <> CHR$(13) AND A$ <> " " THEN B$ = " " : REM Convert CR to space
88  PRINT D$;"WRITE";N$
90  PRINT B$; : GOTO 110
100 PRINT D$;"WRITE";N$
110 PRINT A$;
120 GOTO 70
130 PRINT D$;"CLOSE"
140 END
```

After you have passed the text file through this "pre-processor", you can transmit it with the first program.

LaserWriter Driver: Laser Prep and PostScript

Revised: 3/4/90
Security: Everyone

LaserWriter Driver: Laser Prep and PostScript

=====

Article Created: 20 February 1990
Article Last Reviewed: 15 July 1992
Article Last Updated: 15 July 1992

The Apple LaserWriter driver is a program that takes a print record created by an application and the Macintosh Print Manager and converts this print record into a format appropriate for a LaserWriter. The driver captures all QuickDraw calls and converts them into equivalent PostScript calls and commands.

Until System 7, abbreviations for long PostScript commands and routines for repetitive and common tasks went into a dictionary of definitions called Laser Prep, created for two reasons:

- Unlike printer software that requires commands of a single byte, PostScript accepts commands that are a series of ASCII characters.
- There are some common tasks that needed to be done repeatedly by virtually all documents sent the LaserWriter.

Once Laser Prep downloaded itself into the LaserWriter when the LaserWriter was initialized, the LaserWriter driver didn't have to generate and send redundant and unnecessary information with each printing. Translating, sending, and printing a document was much quicker with a LaserPrep file than without one. However, each time a Macintosh using a different version of Laser Prep or of the LaserWriter driver sent a print job, Laser Prep was forced to download again and reinitialize the printer. Under System 7, the prep information is downloaded to the printer with each print job.

If you look at a PostScript text file generated from the Macintosh, you'll see that almost all the PostScript commands sent by the driver are not abbreviated commands. These abbreviations were sent to the LaserWriter, which (using Laser Prep with pre-System 7 versions of the driver) had the prep file resident from the first printer session after startup. The prep

..TIL02229-LaserWriter_Driver-Laser_Prep_and_PostScript_(TA36965).pdf

file took these abbreviated commands and, through its dictionary, which is actually almost the entire prep file, provided full PostScript commands to the LaserWriter.

The requirements do not differ from application to application, because they all (all that use the Apple LaserWriter driver) generate the abbreviated PostScript commands. Applications - PageMaker for example - use their own prep and driver files, especially if they perform their function differently than the Apple drivers. The end result is that all full PostScript commands are common to all PostScript printers.

The Laser Prep header file is found at the beginning of the PostScript text file that can be generated by the LaserWriter driver instead of printing. You can create this file under System 7 simply by clicking "PostScript File" instead of "Printer" in the Destination option of the Print dialog box. Under System 6.x, click Okay in the Print dialog box and then hold down Command-K until the Print Status dialog tells you it is creating a PostScript file. This will create a PostScript file with the Laser Prep header (hold down Command-F instead to generate a PostScript text file without the header under System 6.x or earlier; this does not work under System 7).

LaserWriter Plus: Diablo emulation printable area

Revised: 5/9/89
Security: Everyone

LaserWriter Plus: Diablo emulation printable area

=====

This article last reviewed: 4 June 1987

When printing a full page of text in Diablo emulation on a LaserWriter Plus, the top and bottom line of the text may be cut in half, or there may be a similar problem.

In order to get maximum lines per page in Diablo mode, reduce the lines per page (or lines per inch) setting. There is no other workaround for this situation. The margins set in Diablo mode are the print engine's margins and cannot be reset.

For a long time, there's been a known bug in Diablo mode that causes margins to be wrong sometimes. There has been no fix for it because the problem cannot be found.

Some users may think that when Apple upgraded the LaserWriter and reduced the printable area, Apple neglected to test the Diablo emulation. This misconception needs to be cleared up. There's no difference in the margins between a LaserWriter and a LaserWriter Plus in Diablo 630 Emulation Mode. The increased margins come into play only when the printer is being driven by a LaserWriter driver and is using the Laser Prep file that is downloaded from the Macintosh.

AppleWriter IIe DOS 3.3: Ignores Control-O from Apple IIGS

Revised: 6/10/87
Security: Everyone

AppleWriter IIe DOS 3.3: Ignores Control-O from Apple IIGS

=====

The DOS 3.3 version of AppleWriter IIe is incompatible with the Apple IIGS in that it does not recognize a Control-O for the options menu. If you go into the Print/Program Commands menu, you will also notice that all the defaults are set to zero.

Here's a workaround:

1. Boot up with the DOS 3.3 System Master.
2. Take out the DOS 3.3 System Master and insert AppleWriter IIe DOS version.
3. Type BRUN OBJ.BOOT and return
4. When AppleWriter comes up, press the Return Key.
The disk spins, and then the program freezes.
5. Press Control-Reset.
A blank screen should appear.
6. Press Control-Reset.

This should bring the program back. The values in the Print/Program are still zero'ed, but you can access the Control-O menu. Make sure not to press Control Open Apple Reset in steps 5 and 6.

The data line still shows mouse text characters. To correct this, run the Apple IIc patch for the DOS 3.3 version of Apple Writer IIe. With this patch, mouse text characters are removed from the data line.

Interbridge: Using it with 9600 baud modems

=====

This article last reviewed: 4 June 1987

A workaround was developed after trying to get the Hayes Interbridge to work with third party 9600 baud modems, Codex model 2260's, supposed to be Hayes command compatible.

In theory, the Codex modems should work after engineers unplug the 2400 baud modems they were using and plug in the Codex's, properly configured. Unfortunately, the Interbridge seems to look for responses that the Codex does not give.

Listed below are the settings used for the Interbridges and modems.

Equipment

2 Macintosh Plus
2 Interbridges (upgraded ROM's)
2 Codex Model 2260 modems.
Appropriate cables

Bridge Setups

Port S1

Remote Bridge
9600 baud
Async
Leased

Port A1

AppleTalk	On
Net#	Must be <>
Bridge Name	Must be <>
Zone Name	Must be =

Modem Setup

ORIGINATING MODEM

Connect the phone lines to the Audio Line (NOT the LLine) jack.

Rate = 9600 only

Terminal

Format = Async

Char Length = 10

DTR = 108.1 (Note: this tells the modem to dial on Interbridge power up. If you use 108.2 you will have to select one of 8 preset numbers to dial.

RTS = Normal

RTS/CTS Delay = 0

DCD = Normal

DSR = High

Modify Audio

Answer = Auto

Default Dial = 1 (or whichever preset number you want)

Line = Dial

Modify Modem

Mode = External

Clock = Internal

AutoRetrain = On

Disconnect = PSTN

Auxiliary

This is where you enter/view/set your phone numbers.

ANSWERING MODEM

Same setup as the originating modem except the default dialer is off.

Overview

Once the above setup is completed, any time the originating Interbridge is powered on, the modem will call the other Interbridge and begin operation.

Hard Disks: Head parking

Revised: 9/16/88
Security: Everyone

Hard Disks: Head parking

=====

This article last reviewed: 2 June 1987

Disk parking or head parking is a feature considered essential by those who concern themselves with the long term reliability normally associated with a hard disk. Since a 'parked' head cannot 'land' on the data area, the disk becomes more reliable in terms of data integrity. Assuming the head parks in a non-data area, the disk is safer to use and move.

Apple 20 megabyte hard disks (Hard Disk 20 and SCSI HD20SC) don't have a park function. There is no park track for head resting on these hard disks.

However, when the drive is not powered up, all hard disks have braking, caused by the inertia of the head's stepper motor. If the heads don't retract, their stepper motor's inertia has to "put the brakes on them" to keep them in place. If the inertia of the stepper motor is great enough, it's difficult to get the head to land or move during "normal" use and movement. The internal SCSI drives on the Macintosh SE are rated for a shock of 40G's, so the stepper motor inertia there must be relatively significant.

The upcoming HD40SC and HD80SC will have a park function; however, be advised that this park function varies from vendor to vendor.

In other non-Apple hard disk configurations, a particular vendor's hard disk may not park the head in a non-data zone or may have stepper motor inertia that isn't great enough to provide adequate braking.

Apple's ProFile hard disk does have head parking. If the disk isn't accessed for 2-3 seconds, the Apple Profile's heads park in a non-data area.

AppleSoft: INPUT Statement Documentation Error

Revised: 6/10/87
Security: Everyone

AppleSoft: INPUT Statement Documentation Error

=====

The 'BASIC Programming with ProDOS' manual, published by Addison-Wesley, (service part number 030-1119) has an Appendix B which, among other things, lists changes made to AppleSoft. On page 218, the manual has inaccurate information concerning changes made to the AppleSoft INPUT statement:

"The AppleSoft INPUT command has been made more useful. This command always reads an entire line of text from a file. As before, multiple variables in an INPUT statement are assigned strings of characters that are separated by commas in the input string. When you use ProDOS, the last variable in the INPUT list is assigned all the remaining characters in the line, including commas and colons. This means that you can now use a single INPUT statement, such as 10 INPUT XX\$, to read any arbitrary string of characters."

This paragraph is incorrect. The feature mentioned was considered but not implemented due to compatibility problems.

Macintosh: Custom Drivers For Typesetters

=====

Article Created: 5 June 1987
Article Last Reviewed: 1 November 1991
Article Last Updated: 1 November 1991

TOPIC -----

How can I send Macintosh data to a non-PostScript typesetting device?

DISCUSSION -----

Many typesetters, such as the Autologic APS-5, are not PostScript devices. However, if the typesetter is an ASCII serial input device, data can be sent to it by either printing in draft mode or using a terminal package (e.g., MacTerminal). The drawback is that you can't use graphics or custom characters.

An alternate solution is to have a custom driver written for the typesetter.

For more information on having a custom driver written, search on "GDT SOFTWARES".

LaserWriter: How To Make It Coin Operated

Revised: 11/10/88
Security: Everyone

LaserWriter: How To Make It Coin Operated

=====

This article last reviewed: 10 November 1988

To connect a coin-operated switch to the LaserWriter, try setting the paper tray sensor switches to a "tray out" condition (i.e., no paper tray in the LaserWriter). When a coin is inserted, check for voltage at the paper feed rollers' solenoid (this way you know a sheet of paper has been ejected from the paper tray). Then, reset the the printer to the "tray out" condition until the next coin is dropped.

The connections for the three paper tray micro-switches are at locations J214-2, J214-4, and J214-6 on the DC controller board. The paper feed solenoid is connected at locations J210-3 and J210-4, also on the DC controller board.

Keep in mind that any modifications to the LaserWriter will void any warranty or AppleCare coverage.

AppleLine Cables: How to get and fit them

Revised: 8/19/87
Security: Everyone

AppleLine Cables: How to get and fit them

=====

The need AppleLine cables has finally been met (if you don't mind the AppleLine under your Macintosh Plus or Macintosh SE) by Product A9M0333, the Apple IIGS Adapter Cable.

The Adapter Cable is a female DB-25 with a circular 8 on one end. The only drawback is the cable's length (about 8 inches). Removing the screw and nuts from the cable lets it fit fully into AppleLine's unusual male plug, eliminating the need for a gender bender.

If the cable length is a problem, then Product A9C0314, the Apple II Printer - 8 Cable (smoke), is the answer. It has a male DB-25 (requiring the gender bender) along with the circular 8.

Note: While AppleLine is, logically, located on the Macintosh price list, both of the above cables are listed only on the Apple II price list. You will have to refer to both price lists when ordering this equipment.

Macintosh SE: Slower Performance of Second Disk Drive

=====

This article last reviewed: 8 June 1987

In the Macintosh SE, the upper disk drive (the "external" drive) operates differently from the lower "internal" drive or from any other 800K drive. The upper drive sounds different when moving the head from track to track; it sounds like the head moves three times when seeking.

The upper drive does work, but more slowly, sometimes a third more slowly. The problem resides in the firmware. The software is testing for the source drive at each read whenever the source drive is the upper drive. There have been no fixes for the problem.

LaserWriter: Issuing a restart from an IBM PC XT

=====

This article last reviewed: 8 June 1987

Assuming you are in serial batch or AppleTalk mode and not the Diablo 630 emulation mode, the following PostScript sequence should issue a restart from an IBM PC XT:

```
systemdict/quit get exec
```

This will need to go into a .bat file for output to the printer port. Do not forget that the LaserWriter requires XON/XOFF communication with standard settings of 8 data bits, 1 stop bit, and no parity. If you are using Diablo 630 mode ('special' switch setting), PostScript commands are ignored and treated as text.

Installer: Why it's more useful than copying system files

=====

In general, the Installer is a very flexible program for installing just about anything. Since the Installer is designed to be programmable, the number and sort of items it replaces can vary, depending on the installer script.

In the case of updating a System or Finder file, the Installer will usually only replace resources it identifies as: 1. Apple's and 2. outdated. This method is better than simply swapping an old System for a new one because it lets you keep custom setups including Desk Accessories, Fonts, and special drivers, like MacServe and InBox.

AppleShare 1.1: Won't Start Up Even Though the Server is Okay

Revised: 10/4/89
Security: Everyone

AppleShare 1.1: Won't Start Up Even Though the Server is Okay

=====

This article last reviewed: 8 January 1988

There is a problem in AppleShare 1.1 that prevents the AppleShare server from starting up even though the server is okay.

AppleShare creates and maintains a file called AppleShare PDS, which stands for "AppleShare Parallel Directory Structure." This "Parallel Directory" stores information about files, such as AppleShare short names and access privileges, that cannot be stored in the standard directory. As you add files to an AppleShare volume, the AppleShare PDS file grows.

The problem occurs when the "AppleShare PDS" file grows beyond one megabyte (1,048,576 bytes). It's hard to predict how many files you can add to a volume before you reach this limit.

AppleShare's maximum volume is somewhere between 8,000 and 12,000 files. (The variation is due to how the file names are added to the PDS file.) You can check the size of the "AppleShare PDS" file to see how close you are to the one megabyte limit. If you exceed this limit, your server will continue to report an error condition even if you remove enough files to bring the file down below one megabyte in size.

To fix this:

1. Throw away the AppleShare PDS file.
2. Run the AppleShare Admin program and verify access privileges for the volume. This will recreate the "AppleShare PDS" file, which allows your server to start up again. We recommend that your volumes contain no more than 8,000 files.

The next release of AppleShare will fix this problem.

Macintosh: Upgrade for drives over 32MB (1 of 2)

Revised: 10/18/88
Security: Everyone

Macintosh: Upgrade for drives over 32MB (1 of 2)

=====

This article last reviewed: 9 June 1987

Important Note to Users of Disk Drives With Over 32 MB Capacity

It is extremely important that you upgrade to System 4.1 if your Macintosh computer is attached directly to a hard disk with a capacity of 32 megabytes or more.

There is a bug in versions of the system file prior to 4.1 which makes it unsafe to use disk drives larger than 32 MB. Note that there are special instructions for owners of disk drives over 134 MB as well.

-- Instructions for disks over 32 MB but less than 134 MB:

Use the installer to install System 4.1 and Finder 5.5 on the startup disks of all Macintosh Plus, SE, or II computers.

For Macintosh computers dedicated as AppleShare servers, shutdown the server, restart from the Macintosh System Tools disk Version 2.0, and use the Installer to install System 4.1, Finder 5.5, Chooser 3.1, etc., in the server folder on the server startup volume. When the install is complete, you may restart the server Macintosh as an AppleShare server by choosing Restart in the Special menu.

For the Macintosh II, and ideally the Macintosh Plus and Macintosh SE servers too, use the Install program that accompanies AppleShare 1.1. Doing so also updates the System, Finder, Chooser, etc., as well as updating AppleShare to Version 1.1 (neccessary for the Macintosh II).

Instructions for disk drives with 134 MB or more which were initialized with System 3.3 or earlier (creation date January 12, 1987 or earlier):

Since system versions 3.3 and earlier were not capable of correctly formatting disks over 134 MB, you need to reformat the disk with

System 4.1.

1. Backup all information on the hard disk to another device using a file by file backup (the Finder will do). Image Backup utilities are not acceptable, since image restoration will preserve the bad format.
2. Reformat the hard disk using System 4.1
3. Restore the information back to the hard disk using a file by file technique.
4. Update the System and Finder versions to 4.1 and 5.5, respectively.

Macintosh: Upgrade for drives over 32MB (2 of 2)

=====

This article last reviewed: 9 June 1987

-- Special instructions for disks attached to AppleShare Servers:

Updating a disk over 134 MB attached to an AppleShare file server is a bit more complex because access privilege information will need to be manually restored during the update process. Note that updating requires a file by file backup of and restore onto the hard disk, and that all access privilege information will need to be reset after reformatting and restoration. A note below details the difference between file-by-file and image backup.

There are two alternative approaches to the process: Method A, less a burden for the server administrator, requires coordination with all server users. Method B requires little coordination, but may entail a substantial time commitment from the server administrator.

Method A - User participation.

1. Instruct all users of the file server to make backup copies over the network of the information they own on the affected volume(s) using their own local storage resources and to delete their information and folders from the server volume as they back them up.
2. After all users have completed this process, shut the server down, run AppleShare Admin, and make a complete volume report for each volume over 134 MB and make a floppy backup of the users and groups list.
3. Copy all remaining files and folders on affected volumes that you wish to preserve (perhaps belonging to absent employees) to some other storage device using a file by file technique (like the Finder).
4. Restart the server CPU using a floppy disk containing System 4.1, such as the Macintosh System Tools disk Version 2.0, and reformat the disks over 134 MB.
5. Restore the files and folders that you preserved in step 3, if

any, to the reformatted volumes using a file by file restore technique.

6. Insert the AppleShare Server Installer disk and open the Admin Application. Prepare the disk(s) as server volumes. If the program asks for a users and groups file, use the one you preserved on floppy.
7. Once preparation is complete, use Admin to reassign ownership and access privileges to each folder that you restored, if any, to the reformatted volumes using the information in the volume report(s) you created in step 2.
8. Quit Admin, and install system 4.1 in the server folder of the server startup volume, replacing the existing system. Use the installer utility for this purpose.
9. Restart the server, and instruct all users to log on to the server and restore their individually backed up information to the server. Each user must reset access privileges to each folder they own as desired.

Method B - No user participation.

1. Shut the server down, run AppleShare Admin, and make a complete volume report for each volume over 134 MB and make a floppy backup of the users and groups list.
2. Copy all files and folders on affected volumes that you wish to preserve to some other storage device using a file by file technique (like the Finder).
3. Restart the server CPU using a floppy disk containing System 4.1 and reformat the disk(s) over 134 MB.
4. Copy the files and folders that you preserved in step 2 to the reformatted volumes using a file by file restore technique.
5. Insert the AppleShare Server Installer disk and open the Admin Application. Prepare the disk(s) as server volumes. If the program asks for a users and groups file, use the one you preserved on floppy.
6. Using Admin, reassign ownership and access privileges to each folder that you restored to the reformatted volumes using the information in the volume report(s) you created in step 1.
7. Quit Admin, and install System 4.1 in the server folder of the server startup volume.
8. Restart the server.

Note on Backup:

Upgrading Disks over 134 MB which were originally initialized with System 3.3 or earlier requires a file-by-file backup and restore, since the original format was incorrect.

There are basically two kinds of backup: file-by-file and image. File-by-file backup performs its functions through standard file system calls, and backs up a particular file by creating a copy on another storage resource. Only the information in the file is transferred from the original storage device to the backup device. The formatting information on the original device is not transferred to the backup device.

Image backup performs its functions at a much lower level in the system. Image backup backs up a storage device as a series of bits of data, and does not differentiate between data and formatting information on the original storage device. The image backup of a storage device will therefore contain the formatting information of the original, even if it is incorrect. Restoring from an image backup onto a storage device will replace whatever formatting information is there with the formatting information that was in the image backup.

Apple IIGS: Printing to the LaserWriter from AppleWriter

Revised: 7/2/87
Security: Everyone

Apple IIGS: Printing to the LaserWriter from AppleWriter

=====

Applewriter II works correctly on the Apple IIGS, except that you cannot print using the built-in ports to a standard RS-232 serial printer. You can, however, use the ports to print to a Laserwriter or an Imagewriter II over Appletalk. You can also print to either a parallel or serial printer by simply installing a compatible interface card, such as a Super Serial or Parallel card, into one of the Apple IIGS's slots.

To print to the Laserwriter or an Imagewriter II over Appletalk, you must first use the Chooser that comes with the Apple IIGS system disk. Choose the Appletalk printer that you would like to print your documents on, and then exit the program. When you are in Applewriter II, make sure that the last line of your document contains a form feed command. To do this, just type in the following as the last line in your document:

Control-V Control-L Control-V

This command will force the Appletalk Imagewriter and Laserwriter to eject the last page of the document.

For a deeper discussion on how to print to the LaserWriter from the GS, albeit with AppleWorks, see the article in this Library called "Apple IIGS: Printing to the LaserWriter from AppleWorks."

Apple IIGS: What to Check If the Finder is Starting Very Slowly

Revised: 8/28/90
Security: Everyone

Apple IIGS: What to Check If the Finder is Starting Very Slowly

=====

This article last reviewed: 8 January 1988

When the Apple IIGS Finder starts very slowly, perhaps even seeming to be locked up, there are a number of things you can do:

- Limit the number of files/folders at the root level of the hard disk to fifty or less.
- Limit the number of files in any given folder to 50-60. This allows a reasonable number of files in a folder without any undue amount of time opening and displaying the folder. (These 50-60 files within folders can be other folders.)
- Displaying the file names by Name or Date, rather than by icon, take less time.
- Check the Control Panel and be sure there is no RAM set aside for RAM Disk. Memory is needed to build the table for displaying the files. If you have any of the RAM card assigned as RAM Disk, you will take up memory space needed to build this table. Normally this would give you an out of memory error message, but something else may be happening before the error is displayed.

When the Finder is requested to open a window, it must calculate the regions for every file/folder to show, so it knows where in the window it goes, and whether or not to display it, given the current size of the window, not to mention what color it needs to be. This can take a long time. Seven hundred files/folders could take hours to show up in the window on the screen.

Apple IIGS Lithium Battery

Revised: 1/17/92
Security: Everyone

Apple IIGS Lithium Battery

=====

Article Created: 31 Juy 1987
Article Last Reviewed: 17 July 1992
Article Last Updated:

BEFORE YOU START: Familiarize yourself with the Apple IIGS
Technical Procedures.

PROBLEM DESCRIPTION: The lithium battery is leaking and has
contaminated the logic board of the Apple IIGS.

CURE: Do NOT attempt to clean the board. Do NOT install a new
battery. The entire board, with leaking battery, should be
returned to Apple and an exchange module installed in the
customers computer. The logic board should be returned in the
standard anti-static bags and the normal shipping box.

ImageWriter II:Paper Feed and Detection Problems(2 of 2)

Revised: 1/17/92
Security: Everyone

ImageWriter II:Paper Feed and Detection Problems(2 of 2)

=====

This article last reviewed: 29 March 1988

PROBLEM DESCRIPTION: Paper jams or "paper folding" between the paper blade and paper bail assembly with the ImageWriter II.

BEFORE YOU START: There are four major reasons that paper jams occur with the ImageWriter II. Those are: a) the platen release lever is not in the correct position (released); b) possible obstruction(s) in the paper path (labels etc...); c) the paper has become deformed because of its being curved under the platen for an extended period of time; d) the paper guide is defective.

With most rear tractor feed printers it's not possible to just load the paper into the tractors and hit form feed to load the paper. You must guide the paper under the platen, then lock it into the tractors or use the procedure outlined in the IMAGEWRITER II owner's manual page 19. If this is the Problem reported, there isn't any 'fix', rear tractor feed printers don't do this gracefully.

CURE: Use the following procedures to troubleshoot the Problem:

1. Remove the paper from the printer and tear off the first page. Sometimes the first page of perforated paper is deformed from its being curved under the printer for an extended period of time (see Note 1). Reinsert the fresh paper and test the printer. Continue to the next step if the Problem still persists.
2. Check that the platen has been released from friction feed mode. Release the platen if the lever is in friction mode and test. Continue to Step 3 if the Problem still persists.
3. Check for the presence of obstructions in the paper path. One very common obstruction is that of a label that has adhered to the metal blade located under the platen. Clear any obstructions

and test the printer. Proceed to Step 4 if the problem persists.

4. Check the paper guide and make sure that it is not damaged. Sometimes the foil will peel from the plastic part of the paper guide assembly. Remove and replace the paper guide assembly if you find it to be defective. Proceed to the next steps if the problem persists.

Other causes for paper jams on the ImageWriter II.

5. Problem: The tractor assembly can be misaligned causing the paper to feed improperly

Cure: Replace the tractor assembly

6. Problem: The paper out sensor is interfering with the paper path. You can really tell this when you insert a single sheet and the left hand side under the platen is 'tighter' than the right side.

Cure: Adjust the paper out sensor so it sits lower in the platen cradle, but high enough to detect paper out. To adjust the paper out sensor, take a screw driver and bend the sensor downward.

7. Problem: Paper guide is either too close to the platen, or damaged. The silver piece in front of the dot head could be torn

Cure: Replace paper guide

8. Problem: Paper bail is not aligned or one side is loose.

Cure: Adjust paper bail or replace

9. Problem: The metal plate on the left of the platen, which holds the platen in place on the left side is loose or out of adjustment (Technical Procedures, IMAGEWRITER II illustrated parts, page 6.36, part 'A')

Cure: Metal plate needs to be adjusted or tightened

Note 1: This step is listed first because deformity of the paper is quite common. Checking the friction lever is normally the first step performed when troubleshooting most other printers.

If this cure does not resolve the problem, go to the Technical Procedures to obtain a General Troubleshooting procedure for this product.

Apple IIfc: Power Light Flashes

Revised: 7/20/92
Security: Everyone

Apple IIfc: Power Light Flashes

=====

Article Created: 31 July 1987
Article Last Reviewed: 17 July 1992
Article Last Updated: 17 July 1992

BEFORE YOU START: Familiarize yourself with the Apple IIfc
Technical Procedures. Be sure to follow proper ESD procedures.

PROBLEM DESCRIPTION: While using the IIfc, the green 'power'
light above the keyboard begins to flash at a steady rate.
This seems to be the only failure. The computer appears to still
be functional, and the video remains unchanged.

BACKGROUND INFORMATION: The internal power supply requires
the voltage from the power pack to be above a certain limit.
When the voltage drops below this limit, the internal power
supply signals an error to the logic board and begins to
flash the 'power' light until the condition is corrected.
Some common causes of this symptom are: brownouts, custom-
made battery packs with insufficient voltage or low battery
power, or attempting to run the IIfc from an automobile cigarette
lighter while the car is running. Although the Apple IIfc Reference
manual states that the Apple IIfc internal power supply requirements
are from between 9 and 20 volts, anything below approximately
12.5 volts may cause the 'power' light to flash.

CURES:

#1: Verify that the power source is providing the correct
voltage to the Apple IIfc.

#2: Replace the external power supply.

#3: Replace the internal power supply

If problems still continue then refer to the Apple IIfc General

Troubleshooting procedures.

Apple IIGS: Problems setting the RAM Disk

Revised: 8/7/87
Security: Everyone

Apple IIGS: Problems setting the RAM Disk

=====

You may encounter problems if you set your RAM disk to the entire capacity of your RAM card. MouseDesk may be unable to write files to the disk when it gets close to full, and programs run from it may crash. The problem is in the Memory Manager, not in MouseDesk.

Until the problem is corrected, the workaround is not to set the RAM disk size as large as the RAM card. This should be acceptable, as most people need some of the extra RAM for the Tools and for data space for programs (such as AppleWorks 2.0) that recognize it.

LaserWriter: Buffer Space and XOFF Character

Revised: 3/4/90
Security: Everyone

LaserWriter: Buffer Space and XOFF Character

=====

This article last reviewed: 6 August 1987

When the LaserWriter's input buffer fills, it sends an XOFF character to the computer. In some cases, after receiving the XOFF character, the computer can't stop transmitting immediately. This means that if the XOFF character is not sent early enough, characters may be lost.

The LaserWriter sends the XOFF code when there are 100 characters left in the input buffer. If this is not enough, changing to version 2.0 ROMs may help. Those ROMs support DTR as a method of handshaking, which generally operates faster than XON/XOFF.

ImageWriter II Sheet Feeder: Damage During Removal

Revised: 11/10/88
Security: Everyone

ImageWriter II Sheet Feeder: Damage During Removal

=====

This article last reviewed: 10 November 1988

The problem: sometimes the right side of the platen (facing the front of the unit) becomes loose and disengages from its mounting bracket. This can cause intermittent print quality problems.

The cause: while removing the Sheet Feeder, the operator rocks the assembly back and forth to eject it from the printer. This puts pressure on the platen hold-down bracket, bending it in such a way that the platen is loose enough to rise out of the frame assembly. The print head then does not firing squarely on the platen.

Three remedies:

- Remove and straighten the bent mounting bracket, then re-install it.
- Remove the bent mounting bracket and replace it with a new part (# 076-0200)
- Remove and straighten the bent mounting bracket. Drill out the dimple (the raised steel stamping) on the mounting bracket with a power drill and a 3mm bit. You can then mount the bracket with two screws instead of one. Use a SMW 2.6 x 6 screw along with a nut and toothed washer.

LaserWriter: How To Print On Legal-Size Paper Without A Cassette

Revised: 12/3/88
Security: Everyone

LaserWriter: How To Print On Legal-Size Paper Without A Cassette

=====

This article last reviewed: 21 October 1988

It's possible to print on legal-size paper even if you have no legal paper input cassette. (If a letter-size paper cassette is installed, the LaserWriter or LaserWriter II assumes it's printing on letter-size paper.) This procedure assumes your application uses the standard Apple Page Setup dialog.

1. Choose Page Setup from the File menu. Select the US Legal button.
2. Click the Options button.
3. Click the box next to Larger Print Area. This shrinks the "nonprintable" area on the paper. (Without this step, the image is out of registration by 1/3 the length of the paper.)
4. Choose Print from the File menu.
5. Choose Manual Feed in the print dialog box.

AppleSoft BASIC: Random Number Generators

Revised: 8/7/87
Security: Everyone

AppleSoft BASIC: Random Number Generators

=====

Applesoft BASIC includes a pseudo-random number generator, function call RND(x).

If $x = 0$, then the previous random number is returned.

If $x > 0$, then a new sequence of random numbers is generated by taking the previous random number, multiplying by a constant, and then adding the result to another constant. (The multiplication constant is -3490938.41 and the addition constant is -9.47445545 E-9.) Then the high and low bytes of the resulting 5-byte floating-point number are swapped, the exponent is rotated into the mantissa for further "randomness," and the new exponent is set to -1, insuring a number between 0 and 1. The high and low bytes are swapped to insure a random distribution of numbers greater than and less than 0.5.

If $x \leq 0$, then a new sequence is NOT generated, so the multiplication and addition by constants does NOT take place -- only the swapping process, and so on, that follows.

Operating systems have random number algorithms of their own. For details, see the operating system's documentation.

AppleShare: Why Verifying the Server Can Take So Long

=====

This article last reviewed: 29 March 1988

When an AppleShare server is started up, it initiates a two-pass process that ensures that the PDS (Parallel Directory Structure) is valid. During the first pass, it makes sure that for every entry in the PDS, there is a corresponding entry in the catalog. On the second pass, it does the opposite. A server with a very large number of files can takes an hour or more to verify.

If this interval is unacceptable, turn off the server less often. To blank the screen when you don't need to see it, turn down the screen intensity or install a desk accessory that blanks the screen automatically after a period of inactivity.

Apple IIGS Finder: Description of Features and Some User Tips

Revised: 8/28/90
Security: Everyone

Apple IIGS Finder: Description of Features and Some User Tips

=====

This article last reviewed: 12 January 1988

The Apple IIGS Finder brings much of the power of the Macintosh Finder to the Apple IIGS. It lets Apple IIGS users use a 'desktop' interface for launching applications and performing file manipulation. The Apple IIGS Finder works only on an Apple IIGS with a mouse and at least 512K of memory.

Some of the features of the Apple IIGS Finder are:

- icon representation of volumes, disk files, and the trash can.
- menus: Apple, File, Edit, View, Special, and Color.
- online Help available in the Apple menu.
- choice of colors for individual volume and file icons.
- the Put Back function lets the user return files that have been thrown in the trash can or recently moved to the desktop back to their original locations.
- a Preferences option in the Special menu provides six options (all of which default to 'on'):

Display help for dimmed commands. If this box is checked, users can select a greyed-out menu option, and get help on why that option is currently not available.

Double-check before removing files and folders. If this box is checked, a dialog box requests verification before files or folders are deleted.

Color selected icon's background instead of its outline. If this box is checked, the selected icon's background is colored instead of its outline. It is personal preference, but the default -- background color fill -- is easier to see than a colored outline

Save Finder information onto disk. If this box is checked, the Finder creates a file called FINDER.DATA that records the window position and size of all open windows. Another file, called FINDER.ROOT, remembers what windows were open on the desktop when the disk was ejected. If for some reason you want this data not to be recorded, don't check this box.

Hide the Finder's data files. If this box is checked, when a window is opened, the default is to not display the FINDER.DATA and FINDER.ROOT files. If you want them displayed, don't check this box.

Do a smart block copy. If this box is checked, the default mode when copying disks of the same size is to copy only those blocks that contain information (this speeds the process). To copy all blocks, regardless of whether they contain information, don't check this box.

Users familiar with the Macintosh Finder may find the following tips useful when using the Apple IIGS Finder:

- After making a working copy of the original Apple IIGS System Disk 3.0, unlock the working disk. If you don't, the window positions and icon arrangements won't be saved to disk.
- When a 5 1/4" disk is inserted into the drive, there is no way for the Apple IIGS Finder to know it is there, unless you tell it. There are now 5 1/4" disk drive icons on the desktop, directly below any other volumes that are online. When a 5 1/4" disk is inserted, double click on its icon so the Finder can recognize the disk.
- If a volume is brought online while there is another volume of the same name already on the desktop, a dialog box warns the user that the volumes have the same name the operation is cancelled. The disk is not ejected, and the volume does not appear on the desktop. The best thing to do after receiving such a message is to eject the disk by hand.

Security: Everyone

Macintosh II: Loose Speaker Brackets

=====

Article Created: 10 November 1988
Article Last Reviewed: 26 June 1992
Article Last Updated: 17 June 1991

TOPIC -----

Under some conditions, the brackets do not adequately secure the speaker to the lower pan in the Macintosh II. If the Macintosh II is handled roughly during shipping, the speaker may break loose, while the wire harness usually stays connected to the board. The speaker then swings around inside the computer, possibly cracking the main logic board or causing a hazardous short.

DISCUSSION -----

Use a wire butterfly snap hold device similar to the Apple IIe speaker hold down assembly. In fact, the Apple IIe speaker hold down device could be reworked to be used in the Macintosh II. The existing support bars around the speaker can accommodate the wire butterfly snap hold device adequately.

Macintosh: Maximum Number of Digits

Revised: 5/10/89
Security: Everyone

Macintosh: Maximum Number of Digits

=====

A customer asks: "What is the largest number of digits that can be represented in a number on the Macintosh?" The answer depends on what is meant by "digits."

Binary Digits

The maximum number of binary digits is 63. A number this large can be achieved with both the comp data type and the extended data type. In the case of the extended data type, a 15-bit exponent is part of the number.

Decimal Numbers

The maximum representable number in the extended data type is $2^{\text{exponent } (16383) * (1.1 \text{ recurring } 63 \text{ times})} = 1.1\text{E}4932$. This number is 4,933 decimal digits long.

In terms of numbers not represented in a floating point extended data type, but one of the other data types, then the maximum decimal digit is $2^{\text{exponent } 63}$, approximately equalling $9.2\text{E}18$, which is 19 decimal digits.

For More Information

See the "Apple Numerics Manual: Standard Apple Numeric Environment," (copyright 1986, ISBN 0-201-17741-2) page 14.

Note: programming languages may further limit the data types available to the programmer.

Macintosh II and Macintosh IIfx: Guided Tour Disks (1/95)

Revised: 2/2/95
Security: Everyone

Macintosh II and Macintosh IIfx: Guided Tour Disks (1/95)

=====

Article Created: 10 August 1987
Article Reviewed/Updated: 2 February 1995

TOPIC -----

The following is an explanation why the Mac II Guided Tour disk will not launch in some situations.

DISCUSSION -----

On a 1 megabyte Macintosh II, the Guided Tour disk will not launch if the Monitors control panel setting has been changed to:

1. Colors
2. 16 shades/levels
3. or both

The additional RAM required by Color QuickDraw for data manipulation causes the memory available for the Guided Tour to decrease below the required 960K. The shipping default settings are Black & White and 2 colors.

On a Macintosh II with 2MB of RAM, even with the RAM Cache set to 1536K and Monitor control panel set to 256 Colors, the Guided Tour always boots. RAM Cache settings are ignored by the Guided Tour system file.

ImageWriter LQ: Using it with a Macintosh

Revised: 8/21/89
Security: Everyone

ImageWriter LQ: Using it with a Macintosh

=====

This article last reviewed: 10 August 1987

The ImageWriter LQ recognizes output from the Macintosh ImageWriter driver, but, for better results, use the new ImageWriter LQ driver. This driver has options similar to those found on the ImageWriter driver:

- "draft" sends ASCII information to the printer
- "faster" prints 72 x 72 dpi
- "best" prints 216 x 216 dpi

If sheet feeder bin(s) are installed, you can also select the bin for the first page of a document and the bin for the remaining pages. However, those applications that treat each page as a separate document will not be able to take advantage of this feature, since each page will be seen as "Page 1" of a new document.

An AppleTalk ImageWriter LQ driver is also available for times when the ImageWriter LQ is connected to an AppleTalk network.

The ImageWriter LQ comes with four disks. One contains the Macintosh drivers mentioned above, and the other three include font files of various type and sizes.

Because the 27-pin head is organized in three rows of nine pins each, the best printing occurs with a font three times larger than the screen font. Therefore, we are shipping 27 point, 30 point, 36 point, and similar multiples of point sizes of fonts in common faces in the ImageWriter LQ package.

Some font families also include italic and bold. When installed in a system file, these defined faces will replace the computed versions of an italic or bold font.

ImageWriter LQ: Description (Discontinued)

Revised: 6/1/94
Security: Everyone

ImageWriter LQ: Description (Discontinued)

=====

The ImageWriter LQ is a 27-pin wide-carriage dot-matrix printer that can produce black-and-white or color output in three different levels of print quality. The three printer qualities are draft, near letter quality (NLQ), and letter quality (LQ).

Optional accessories are a sheet feeder (which can have up to three paper bins) and the AppleTalk card.

To choose line feed, form feed, printer select, and printer quality, there are external switches similar to those on the ImageWriter II.

The power outlet and mini-circular-8 RS-422 port (pinouts identical to the ImageWriter II) are on the back of the printer. Three sets of eight DIP switches on the logic board are used to select baud rate, character set, handshaking mode, etc.

There are three ways to feed paper through the ImageWriter LQ: friction feed, pull tractor feed, or push tractor feed. Continuous tractor feed paper can be fed through the back of the printer, using either push or pull tractor feed, or paper can be fed from the bottom of the printer and pulled through by tractors behind the platen. The pull tractor option will help correct the problem seen in the push tractor mode of the ImageWriter II which jammed paper against the printer head and paper bale. The ImageWriter LQ has two paper sensors: an optical sensor is used when paper is fed from the back of the printer, and a mechanical sensor is active when bottom paper feed is used.

While the printer has a 5K print buffer, it can accept a larger buffer either on the logic board or on an option card. However, neither larger buffer is available from Apple at this time.

Wherever possible, the ImageWriter LQ firmware accepts the same commands as the ImageWriter and ImageWriter II. For example, "Escape E" instructs the ImageWriter LQ to use elite type size, just as it does on the ImageWriter II. Other commands for characters, graphics, and color remain the same, and there is still support for half-height text, superscripts, subscripts, and vertical and horizontal platen and printer head movement. Additional printer commands

support the multiple-bin sheet feeder and high-resolution printing. The ImageWriter LQ does not support downloadable character sets or MouseText, so those commands have been removed.

ImageWriter LQ firmware contains font definitions in various qualities. Draft printing can be done in any available ImageWriter LQ size, including both proportional and non-proportional fonts. Near Letter Quality can also be obtained in all sizes, either proportional or non-proportional. If Letter Quality is chosen, the firmware must also be instructed to use one of the two proportional fonts, since Letter Quality cannot be printed in a non-proportional size. AppleWorks users must be sure to select "P1" or "P2" as the character size when using Letter Quality on an ImageWriter LQ; otherwise, the printer will use Near Letter Quality and its non-proportional font instead.

ImageWriter II graphic modes are referred to as "standard-resolution graphics" on the ImageWriter LQ. The LQ can print at 72 dpi (dots per inch) in one pass of the printer head, and at 144 dpi in two passes. A third graphics mode, "high-resolution graphics," is accomplished in one pass using 24 pins, and results in 216 dpi both horizontally and vertically. 216 dpi is the maximum vertical dot resolution, although the printer may achieve up to 320 dpi horizontally.

Article Created: 10 August 1987
Article Reviewed/Updated: 11 October 1988

Print method: Dot Matrix, logic seek (line by line)

Printing speed: Draft 250 cps at 10 cpi in Draft mode
NLQ 90 cps at 10 cpi in NLQ mode
LQ 115 cps in proportional mode

Printing throughput: 25 line per minute in 216 by 216 graphics mode,
bidirectional, 25% duty cycle, 11-inch wide line,
assuming no limitation because of communications
or overheating of the print head

Character format: Draft fixed-width characters - 12 dots wide by 7 dots
high, using every third print head wire and using every
other dot on a horizontal line (1/2 dot method)

Draft proportional characters - Up to 16 dots wide by 7
dots high, using every third print head wire

NLQ fixed-width characters - 16 dots wide by 24 dots high

NLQ proportional characters - Up to 16 dots wide by 24
dots high

LQ proportional characters - Up to 32 dots wide by 24
dots high

Standard characters: 96 ASCII (alphanumeric and symbols)
28 European language characters

Vertical dot spacing: 1/216 inch

Printed line length: 13.6 maximum

Horizontal pitches:	Characters per inch	Characters per line
---------------------	------------------------	------------------------

17	231
15	204
13.4	182
12	163
10	136
9	122

Input buffer: 5K (Though expandable up to 64K, Apple has not yet implemented this capacity.)

Paper feed direction: Forward and reverse

Line spacing: 1/144 to 99/144 inch, selectable in increments of 1/144 inch

Line feed speed: Maximum 24 lps at 6 lpi

Paper width: 3.5 to 15 inch pin to pin

Paper thickness: 0.051 - 0.55 mm (0.002 to 0.028 inch)

Paper feed method: Selectable, friction, push tractor, or pull tractor feed

Paper types: Single sheets

Continuous paper hole centers 3.5 - 15.0 inches

Ribbon: Cassette containing black inked fabric ribbon, continuous

Optional four-color ribbon: black, yellow, magenta, cyan

Ribbon life: 4 million characters (black)

1 million characters/band (color)

Power options: North American 120 V AC +/- 10%, 60 Hz

Universal	100 V AC +/- 10%, 50/60 Hz
	120 V AC +/- 10%, 50/60 Hz
	140 V AC +/- 10%, 50/60 Hz
	200 V AC +/- 10%, 50/60 Hz
	220 V AC +/- 10%, 50/60 Hz
	240 V AC +/- 10%, 50/60 Hz

Power consumption: Operating - 180 W maximum

Standby - 20 W maximum

Data input form: 8-bit serial: 1 start bit, 8 data bits, and 1 stop bit
(no parity bit), asynchronous

Data output form: 8-bit serial: 1 start bit, 8 data bits, and 1 stop bit,
no parity, asynchronous

Transmission speed: 1200, 4800, 9600, or 19200 baud set by DPI switches

Printer connector: minicircular 8-pin socket

Cable connector: minicircular 8-pin plug

Weight: 17 kg (38 lb)

Dimensions:	Width	Depth	Height
	590	380	130 mm
	23.2	15.0	5.12 in

Ambient temperature in degrees:	Celsius	Fahrenheit
- Operating	10 to 40	50 to 104
- Storage (1 year)	-40 to 47	-40 to 116
- Transit (72 hours)	-40 to 65	-40 to 149

Humidity: Operating- 20% to 95% relative, noncondensing
Storage (6 mo.) - 10% to 95% relative, noncondensing

Operating acoustics: 55 dBa maximum sound pressure at typical operator distance

Print head life: 400,000,000 wire fires (approx. 200,000,000 characters)

Macintosh: System Tools 5.0 with MultiFinder

Revised: 8/7/91
Security: Everyone

Macintosh: System Tools 5.0 with MultiFinder

=====

Article Created: 10 August 1987
Article Last Reviewed: 2 February 1991
Article Last Updated:

TOPIC -----

This article outlines the use and features of Macintosh System Tools 5.0.

DISCUSSION -----

System Tools 5.0 files were intended for use on the Macintosh Plus, Macintosh SE, and Macintosh II. Due to increased memory demands caused by larger system files and MultiFinder, these tools cannot be used reliably on a Macintosh with 128K or 512K, or on a Macintosh XL. In Version 5.0 of Macintosh system software, the System, Finder, and CDEV files were revised to support MultiFinder and to expand Macintosh II features.

System 5.0

The following list summarizes the changes made to Macintosh System files in Version 5.0:

- Color support for the Macintosh II
- More fully-implemented Palette Manager
- Upper drive on the Macintosh SE used at the same speed as the lower
- Command-Shift-1 and -2 (and all FKEYs) work properly under Excel
- No stray dots appear when outlined text is move
- Releases previously-used memory correctly when re-initializing the ADB port

- Supports a color desktop pattern through the Color code
- Supports color text highlighting

The Finder

- Supports color; a new menu appears when Finder 6.0 is used on a Macintosh II to let the user select the color of an icon or folder.
- Supports MultiFinder

The LaserWriter Driver

- Supports MultiFinder
- Clips the right edge of bitmaps properly

HyperCard v1.0: Specifications (Discontinued)

=====

This article last reviewed: 10 August 1987

Number of stacks: Limited only by available disk or file server storage.
Each stack is one Macintosh disk file.

Maximum stack size: 4096 Megabytes

Number of cards per stack: Limited only by available disk or file server
storage.

Card size: 512 horizontal by 342 vertical pixels

Graphics: Black-and-white bitmaps with opaque and transparent areas.

Text fields per card: Unlimited

Maximum text per field: 32,767 characters

Buttons or links per card: Unlimited

Maximum script length: 30,000 characters

System Requirements

HyperCard will operate on Macintosh Plus, Macintosh SE, or Macintosh II that has:

- at least 1MB of RAM
- a hard disk, or two 800K disk drives
- Finder 5.3 or later
- System 3.2 or later
- LaserWriter 4.0 or later

If you wish to operate other applications simultaneously with HyperCard using MultiFinder, your system should have at least 2MB of RAM.

NuBus: Apple's Implementation

Revised: 7/21/92
Security: Everyone

NuBus: Apple's Implementation

=====
Article Created: 10 October 1987
Article Last Reviewed: 21 July 1992
Article Last Updated:

TOPIC -----

This article discusses the features of NuBus™ and how Apple's implementation differs from the original design.

DISCUSSION -----

The major advantage of NuBus is its simplicity in system configuration and protocol. A simple handshake protocol between master and slave enables modules or boards with different speeds to communicate. There are no interrupt lines. Each module can interrupt a processor by writing into an address space area monitored by that processor. NuBus also relies on only one main bus, in contrast to more complicated competition, such as VME and Multibus II.

NuBus is independent in terms of system architecture and CPU. Because each board has its own ROM, there is no need for jumper and switch settings. It has synchronous bandwidth of 10 MHz and is easily adaptable to asynchronicity. (Its transactions may be a variable number of clock periods long.) It requires fewer signal lines than all other advanced buses.

The major change Apple made to the NuBus was a signal change with the NMRQ (non-master request). It is a dumb interrupt that allows a slave to interrupt without being the bus master. Apple's NuBus implementation adds interrupt lines to the 68020 from each of the slots.

NuBus data-transfer signals are all three-state and include control, address/data, and parity. Apple also does not implement the parity checks.

Another major change has to do with the form factor: Apple uses smaller

cards.

Although NuBus is designed for 32-bit addressing modes, the Macintosh II logic board is typically set in a 24-bit mode. The current Operating Systems Utilities portion of the firmware will translate to accept previous 24-bit addresses.

The NuBus can handle 16 slots to provide expansion capabilities for Ethernet, terminal, serial and parallel devices, video output, and other processors and coprocessors. Apple's design implements only six.

Here are some articles on NuBus:

- "Battle of the Buses for 32-bit Systems," Systems & Software, 9/84
- "Bus Structure Eases Multiprocessor Integration," Computer Design, 6/84
- "Synchronous 32-Bit Backplane Buses Open Up Distributed System Design," EDN 6/84

For basic information such as pinout and signal descriptions, glossary of terms, addressing, and capabilities, search on "NuBus".

AppleShare 1.0/1.1: Lost Server Volumes

=====

Article Created: 13 August 1987
Article Last Reviewed: 3 April 1992
Article Last Updated: 3 April 1992

TOPIC -----

The following describes a problem with server volumes being reported in need of repairs in error.

DISCUSSION -----

When using AppleShare 1.1, the Finder may complain that the server volume needed minor repairs and then reported that the volume couldn't be fixed. Unplugging the AppleTalk connector makes the problem go away.

One way to get into this situation is to have a volume to which access has been completely denied after the volume is marked for mounting at start up. When the Finder tries to access the volume, it gets an immediate error. The Finder then tries to create a new Desktop file, which fails also, resulting in a final error message and no trace of the volume on the Desktop.

One fix: use the Chooser to select the server volume then deselect the box labeled "Mount at Startup time." That should stop the volume from being mounted without access to the root, causing the Finder no further difficulties on the next startup.

Another solution: throw away the "AppleShare Prep" file in the System folder, causing all startup information to be lost.

Future versions of AppleShare will check the root of the volume for accessibility before mounting the volume, the way the chooser already does (indicated by greying out the volume name in the volume list).

Macintosh SE Hard Drive Systems: HD SC Setup Version 1.3

Revised: 8/7/92
Security: Everyone

Macintosh SE Hard Drive Systems: HD SC Setup Version 1.3

=====

Article Created: 13 August 1987
Article Last Reviewed: 7 August 1992
Article Last Updated: 7 August 1992

TOPIC -----

A problem was discovered when HD SC Setup Version 1.3 was used to initialize a hard disk inside certain Macintosh SE computers. This recalibration problem may have, in rare cases, caused a loss of data. The article below provides more information.

DISCUSSION -----

The Macintosh SE production units which MAY experience this problem have serial numbers beginning with:

F721,
F722, or
F723

The fix for this is to use Version 1.4 or higher of HD SC Setup.

Production units with serial numbers F724 and up didn't have this problem and could be initialized with either version 1.3 or 1.4 of HD SC Setup.

HD SC Set Up 1.4 was shipped with production units starting in early July of 1987.

Customers should upgrade to HD SC Set Up 1.4 or higher (and discard version 1.3) to ensure compatibility with all hardware configurations. Any Macintosh SE that has been initialized with version 1.3 should be updated using version 1.4 to avoid loss of data in the future. If a Macintosh SE hard disk system is serviced, the hard disk must either be updated or re-initialized with HD SC Setup 1.4.

Version 1.1 may continue to be used -- with Rodime drives only -- but due to its lack of versatility, its use is not encouraged.

BACKGROUND

The Macintosh SE originally contained:

- SCSI hard drives made by Rodime
- HD SC Setup version 1.1.

When MiniScribe became a second source of drives, HD SC Setup version 1.3 was required, because version 1.1 would not recognize or initialize MiniScribe drives.

Version 1.3 was designed to be used with both Rodime and MiniScribe drives. Unfortunately, version 1.3 exposed a bug in the Rodime drive controller. Version 1.3 turned on Rodime's head recalibration feature, which activated every 20 minutes and took 5 seconds. If the Macintosh SE user attempted to save data onto the hard disk during that time, the drive controller chip interrupted the recalibration. However, the recalibration wasn't terminated properly, and scrambled data was written to the sector over which the drive head resided. The user would notice a problem at some later date, when attempting to access the file containing the scrambled sector.

HD SC Setup version 1.4 or higher works properly on both Rodime and MiniScribe drives.

Disk Cache: Macintosh compared to IBM PS/2

Revised: 8/13/87
Security: Everyone

Disk Cache: Macintosh compared to IBM PS/2

=====

A caching device driver is included with the new IBM PS/2, models 50-80. This cache uses a technique that fetches either 2, 4, or 8 sectors (user selectable) when an I/O is issued for a single sector. This method appears to achieve significant performance improvements with relatively small cache sizes. Some have asked whether Apple (or other vendor) is looking at improving the Macintosh's disk performance this way.

Apple's disk caching is not done like IBM's, for two reasons. The first has to do with hardware: the IBM can access a multiple number of blocks in just about the same time it can access just one. We can't do that with our drives; we have to monitor the reading of each block.

Second, Apple has a very complicated file format and directory structure that can't compare to the IBM disk format. The Macintosh is constantly loading in small resource segments (often much smaller than one block) and maintaining a complex B-tree catalog structure. Our disk cache is optimized for this type of structure.

Basically, the way the cache works is to remember recently-written blocks of data. It can be thought of as a "post-written" system, rather than a "read-ahead" system. If we need that information again soon, we can retrieve it from the cache rather than from disk. However, we can do some read-ahead, as some hard disk controllers maintain a track buffer, reading in an entire track at once and doling it out to the Macintosh one block at a time.

ADB Keyboard: Cure for 'Dead' Keyboard

=====

Some users have reported that their ADB keyboard are sometimes 'dead' (though the mouse works fine) when they start up a Macintosh II or SE. One reported cure has been simply to unplug the keyboard then plug it back in.

Caution: this fix works only if the mouse is plugged into the second ADB plug on the back of the computer. If the mouse is plugged into the keyboard, the fix (unplugging the keyboard then plugging it in again) crashes the system.

Apple Extended Keyboard: Key Codes

=====

Article Created: 13 August 1987
Article Last Reviewed: 25 June 1992
Article Last Updated:

TOPIC -----

Are the key codes for the Apple Extended Keyboard different from those of the Apple Standard Keyboard?

DISCUSSION -----

The key codes for the Apple Extended Keyboard differ slightly from those of the Apple Standard Keyboard. The following list includes only those keys whose codes are different from the Apple Standard Keyboard:

F1	7A
F2	7B
F3	63
F4	76
F5	60
F6	61
F7	62
F8	64
F9	65
F10	6D
F11	67
F12	6F
F13	69
F14	6B
F15	71
HELP	72
HOME	73
PAGE UP	74
PAGE DOWN	79
DELETE	75

END	77
CURSOR UP	7E
CURSOR DOWN	7D
CURSOR RIGHT	7B
CURSOR LEFT	7C

Application software should NOT be designed so that it depends on these key codes -- because they will probably change. These codes are used by the application and are not necessarily what the keyboard actually puts out. Any unused codes not listed here are not yet defined and should not be used.

Key codes for the Apple Standard Keyboard are found in the "Macintosh Family Hardware Reference."

AppleWorks: Problems Loading, Uploading, or Saving

Revised: 8/13/87
Security: Everyone

AppleWorks: Problems Loading, Uploading, or Saving

=====

Three of the most common questions about AppleWorks deal with files not loading, saving, or uploading properly to a base for electronic mail or messages. The solution is often simple. Before panicking, consider the following solutions.

File won't load - file not found

First, be sure you're not be trying to open more files than AppleWorks allows. AppleWorks allows no more than twelve files on the desktop at any one time -- less in the case of large files or limited memory.

If the file name appears in the directory, but AppleWorks can't access it, the file or the subdirectory may be damaged. To logically isolate the problem, use a copy utility (System Utilities 2.1.1 or the GS System Utilities 1.1) and move the suspect file to another directory and attempt to load it from there. If it will not load from the new directory, then the file itself is corrupted and the data is lost -- unless it has been backed up.

If the file is moved to a subdirectory, and it loads correctly from there, the original subdirectory is damaged. Copy all files in the subdirectory to another area, then delete the damaged subdirectory.

If you are using a floppy drive, check the disk and make sure it isn't damaged: it's far less expensive to discard a disk and use a new one than to continue losing data! If you are using a hard disk, and you discover a problem, you will want to back up the drive and reformat it.

File won't save - diskette is full

The most common reason for a file not saving is the tendency to overfill subdirectories. While ProDOS allows 51 files on the Root Directory, and an unlimited number in subdirectories, AppleWorks permits only 130 files in a directory. Veteran AppleWorks experts limit subdirectory entries to 30 or less. While this is not a major problem for 5.25" drive users, it can

become a problem with larger-capacity drives.

Make sure that you are not saving all your files in one area. Subdirectories can be used effectively to organize and catalog your files.

AppleWorks text file won't upload

Some systems, such as CompuServe(tm), require both a Carriage Return AND a Linefeed at the end of each line in order to upload files correctly.

In AppleWorks, Version 1.3 or earlier, writing an AppleWorks document out as text (ASCII) file, or using the AppleWorks option of "Printing to a Text (ASCII) File" will result in:

- A carriage return in the text file wherever there is a Carriage Return in a word processor document.
- A carriage return following each entry in a data base report.
- A carriage return following each cell when working with a spreadsheet document.

To get that elusive Line Feed, the work-around is to configure a Custom Printer using the "Add a Printer" option in AppleWorks. Name it "Upload" or some other appropriate name that will remind you of its purpose. Choose the SilentType printer. Change the specifications to add a Line Feed after each RETURN, [1. Needs line feed after each RETURN], and save this printer configuration to disk.

To convert an AppleWorks file to an ASCII file with the required Carriage Return/Line Feed line termination, simply print your document to "Upload." The resulting file will then upload properly.

AppleWorks 2.0 AUTOMATICALLY adds Carriage Returns at the end of each line, but you will still have to add Line Feeds with the above procedure.

Summary

Remember the three rules that will keep you out of trouble:

1. Back up your files frequently.
2. Back up your files FREQUENTLY.
3. BACK UP YOUR FILES FREQUENTLY.

AppleFax Modem: Overview and Firmware

Revised: 8/3/89
Security: Everyone

AppleFax Modem: Overview and Firmware

=====

This article last reviewed: 9 August 1988

Overview

The AppleFax Modem allows Macintosh users to send and receive Fax files/documents with the huge installed base of Fax machines currently used by most businesses. In addition to its Fax capabilities, the AppleFax Modem allows 9600 baud file transmission of Macintosh software with other AppleFax Modem users.

The AppleFax Modem's case is exactly the same size as the Apple 3.5" disk drive, letting the two products be stacked. The AppleFax Modem is compatible with Fax Group 3 ONLY (some early-release manuals erroneously\state that the modem is compatible with Fax Group 2 as well). The firmware in this unit is a subset of the Hayes-compatible firmware in the Apple Personal Modem.

Availability

The AppleFax Modem will be sold only by authorized Apple Desktop Communications dealers.

AppleFax Firmware

The command set in the AppleFax Modem firmware is a subset of the Hayes command set used in the Apple Personal Modem, with some additional Fax only 'S' registers. The new AppleFax Modem registers are:

- S14 Error Rate / Contains a value that indicates the number of erroneous transmissions that occurred in the last 256 transmissions.

- S32-S64 Modem Chip Set / These registers map to the R96 Fax compatible modem chip set contained in the AppleFax Modem as follows:

Registers S32-47 Bank 0 registers 0..15

Registers S48-63 Bank 1 registers 0..15

The firmware in the AppleFax Modem is compatible enough with the Hayes protocol that it should run with most communication applications (MacTerminal, for example) with no problem. This will allow you to transfer Macintosh files, type messages back and forth with the other AppleFax Modem owner, and in general become familiar with the command set of this modem.

The communication application must follow these guidelines:

- Handshaking CTS (Clear To Send) or RTS (Return To Send)
- Local Echo Echo off
- Duplex Full duplex
- Bits 8 data bits, 1 stop bit and 1 start bit.
- Baud Rate 9600

AppleFax Modem: Hardware Description (Discontinued)

Revised: 6/1/94
Security: Everyone

AppleFax Modem: Hardware Description (Discontinued)

=====

On the back of the AppleFax Modem, you will find:

- On/Off Switch
- Two line jacks, phone line / phone set
(RJ-11 type, identical in function)
- Two minicircular 8-pin serial ports, Pass through / Fax to Mac
(Allows pass through to second serial device from one Mac port)
- One 7-pin DIN power connector
(+5dc, -5dc generated within unit, +12dc, -12dc)
- Security cable socket
(Newer, smaller version of security socket)

The power source is external, similar in function and size to the Apple IIc power supply, but with a 7-pin power connector instead of 5-pin. There are also two LED indicators on the front of the unit, one yellow and the other green. These indicate the state of the pass through port on the back of the AppleFax Modem. With the yellow light on, the AppleFax Modem is disabled and you're passing through the serial data to the device (usually an Apple Personal Modem) plugged into the 'phone port' (pass through) on the AppleFax Modem (Note: AppleTalk devices cannot be used on the pass through port.) With the green light on, the serial data is going directly to the AppleFax Modem and the pass through port is disabled. The button located between these two LEDs lets you toggle between the two states. There is no software control of this function.

There is also a sliding control on the right side of the unit. This sliding control is used for volume adjustment, the detent being a default volume level. This unit behaves very much like the Apple Personal Modem when dealing with the speaker. The DTMF tones are passed through to the speaker, as well as the connection 'tones,' until the attempt at a connection is successful and both Fax units sync up, shutting off the speaker. Beyond that, there are the same ATM commands available for the user to adjust for different speaker behavior. The speaker is located on the bottom of the case, with slots for the sound to

come out.

AppleFax Modem: General Information

Revised: 12/17/91
Security: Everyone

AppleFax Modem: General Information

=====

Article Created: 14 May 1991
Article Last Reviewed: 7 August 1992
Article Last Updated:

TOPIC -----

This article provides information about the AppleFax modem. Apple no longer sells the AppleFax modem, but it is still supported.

DISCUSSION -----

The AppleFax Modem shipped with two types of software: the resource file and the application. The easiest way to send a Fax is via the "AppleFax Modem" resource file put in your System Folder. With this resource, you can print, just as you do with a laser printer.

The AppleFax application goes beyond the resource, sending multiple Fax messages to multiple addresses at pre-set times. The application also makes a Macintosh file transfer rate 9600 baud possible.

AppleFax Software

The AppleFax package contains the AppleFax application and the AppleFax Modem resource file disk and three other disks containing LQ Fonts. The AppleFax Modem works very much like the ImageWriter LQ, in that it requires fonts when "printing" that are three times the size of the font on the Macintosh screen. When these LQ fonts are installed in the System file you can use the maximum 200 dpi density of the AppleFax Modem.

When the proper size font is not available, resolution suffers, but the Fax document is still printed to the recipient. As long as the fonts are available when the Fax is sent, even a "normal" Fax machine benefits for the 200 dpi images sent from your Macintosh.

There are two ways to use the AppleFax Modem. The first is via the

AppleFax Modem resource file. Once that resource is dragged into the System Folder and selected via the Chooser as the active resource, you're in business.

The advantage of the AppleFax Modem resource is immediate conversion and sending of the document you have selected. You don't even have to leave the active application to send the Fax. You can select any document from within the Finder and "print" it just as you would to a LaserWriter. When the dialog box appears, you have the option of sending the document immediately ("Printing it") or saving it to disk.

For example, if you plan to use the AppleFax application program to send your multiple Fax documents at 1:00 AM, you would use the "Save Fax To Disk" feature for each Fax you want to send with the application. You must use the resource to convert your Macintosh documents into Fax documents. In turn, you can use this resource from within the AppleFax application. Once you have all the Fax documents saved to disk, you're ready to move on to the "AppleFax" application.

The AppleFax application program for the AppleFax Modem turns your Macintosh into a Fax station. The application does require the full attention of the Macintosh and, therefore, won't run in the background. When you start the AppleFax application, the application presents you with various options. Among the main features of the application are that it

- Sends Macintosh files like Macintosh documents and applications.
- Sends many files or facsimiles to one destination.
- Sends one file or facsimile to multiple destinations.
- Specifies the time for the AppleFax Modem station to send your files or facsimiles.
- Sends your files or facsimiles to another AppleFax Modem station that will temporarily store and then forward the files to their final destination.
- Sends your files or facsimiles and then prompts the other AppleFax Modem station to send its files back to you.

Here's a key difference between using the AppleFax resource and the AppleFax application. With the application you can both receive and send facsimiles. With the resource, you can only convert and send a Fax. The application automatically saves the Macintosh files and Fax documents as they are being received from the sender.

More About the AppleFax Application Program

The two main ingredients in the AppleFax Modem application are "Address Books" and "Envelopes." An address book contains the names of various Fax stations, their phone numbers, and the best calling times. You drag addresses over to "empty" envelopes which then become AppleFax Modem application documents. You can put Macintosh files and previously-created

facsimiles into the envelope. Once that's done, you may either wait for the envelope to be sent at the time indicated, or send it "immediately."

If you choose to have the envelope sent at the pre-set time, it is wise to check the "Activity Report," when you come back. The report tells whether the contents of the envelope were really sent, when, and any other problems encountered.

One important note here. When an entry into the address book is created, one of the choices is whether or not this address belongs to a "normal" Fax machine, or to a AppleFax Modem. This is important, for when you drag your address into an empty envelope, that envelope becomes either a Fax-machine-only envelope or a Fax-document-and-Macintosh-files envelope, for use with other AppleFax Modem stations. If you want to send to separate types of stations in the same session, you can create more than one type of envelope.

Apple IIGS Finder

Revised: 1/18/93
Security: Everyone

Apple IIGS Finder

=====

This article last reviewed: 14 August 1987

Overview

The Apple IIGS Finder is similar to the Macintosh Finder, but with enough variation to make it a uniquely Apple II product. The Apple IIGS Finder works only on an Apple IIGS with at least 512K of RAM.

Availability and Distribution

The Apple IIGS Finder was announced August 11, 1987. At that time, it was anticipated that it would be shipped on the Apple IIGS System Disk, revision 3.0, and be part of the Endless Disk Drive mailing the last week of August. The dealers, in turn, are expected to pass out the new System Disk revision freely to their customers. Technical Communications planned to send this disk out to all our audience around the same time.

The Endless Disk Drive mailing will contain two System Disks, revision 2.0 and 3.0. This is bound to cause some confusion, but it is necessary. The Finder application replaces the DeskTop program that has been on earlier versions of the System Disk, including version 2.0. Since the Apple IIGS Finder requires a 512K configuration, we might leave some people out in the cold with their 256K machines. This way, we are able to give them an up-to-date system disk with the DeskTop program on it, which will run on their machines.

This System Disk revision, including the Finder, will make its way into new Apple IIGS boxes in the beginning of September. Because of current stock on hand, these new systems including the Finder are not expected to hit dealer shelves until late September to mid-October.

If current Apple IIGS owners would like the Apple IIGS System Disk manual that is going to be bundled with the new Apple IIGS, along with the System Disk 3.0, they may order it from their dealer.

Finder Notes and Tips

After making a working copy of the original Apple IIGS System Disk 3.0, unlock the working diskette. If you don't, the window positions and icon arrangements won't be saved to disk.

This Finder allows the user to change and save the color of each individual volume and file icon.

To reach online Help, pull down the Apple menu.

If a volume is brought online while there is another volume of the same name already on the desktop, a dialog box appears, warning the user that the volumes have the same name and that the operation is cancelled. Note, however, that the disk is not ejected, though the volume has not appeared on the desktop. It is best after receiving such a message to manually eject the disk.

If the monochrome monitor is used, be sure to select the Monochrome setting in the Apple IIGS control panel. This will use gray scaling to produce a better overall image.

When a 5 1/4" diskette is inserted into the drive, the Apple IIGS Finder doesn't know it's there -- unless you 'tell' it. There are now 5 1/4" disk drive icons on the desktop, directly below any other volumes that are online. When a 5 1/4" disk is inserted, be sure to click on the respective icon so the finder can recognize the disk.

The Put Back function in the Apple IIGS Finder is the same as the Macintosh Finder's Put Away function. This menu choice lets you return files, that you have thrown in the trash can or recently moved to the desktop, back to their original position.

A major difference between the Apple IIGS Finder and the Macintosh Finder is that the Apple IIGS version has a Preferences option in the Special menu. The Preferences dialog gives you six check-box options, all defaulted to a 'checked' state. They are:

- Display help for dimmed commands

If this option is chosen, the user can select a grayed out menu item, and get information on why that item isn't available.

- Double-check before removing files and folders

If this option is chosen, the Finder will not delete files or folders until the user confirms, via a dialog box, that the files or folders should be deleted.

- Color selected icon's background instead of its outline

This is personal preference, but the default (background color fill) is easier to see than a colored outline.

- Save Finder information onto disk

If this option is chosen, the Finder creates a file called FINDER.DATA that records the window position and size for all open windows. There is also a file called FINDER.ROOT that remembers what windows were open on the desktop when the disk was ejected. If you don't want these items recorded, deselect this check box.

- Hide the Finder's data files

When a window is opened, the default is not to display the FINDER.DATA and FINDER.ROOT files. If you want them displayed, deselect this check box.

- Do a smart block copy

When copying disks of the same size, the default mode for the Apple IIGS Finder is to copy only those blocks that contain information. This speeds up the process. If you want to copy all blocks, regardless of whether they contain information, deselect this check box.

AppleWorks 2.0: Page Numbering limit in Footer and Header

=====

While the documentation says that the limit for page numbering is 512 pages, it is actually 256.

You may encounter a situation where a header is numbered from 255 through 256, and the numbering goes on to 257 and further, whereas a footer starts over after page 256 at page 1. This is a problem in either the documentation or the program.

Apple IIGS: VGC and ROM Upgrade Notes

=====

Article Created: 20 August 1987
Article Last Reviewed: 17 July 1992
Article Last Updated:

The serial number cutoffs given in the August Service and Support Notice to determine which Apple IIGS systems need the VGC and ROM upgrade are incorrect.

Use the first three digits of the serial number on the bottom of the Apple IIGS to determine which of the two upgrades a computer needs:

- when the first three digits of the computer's serial number are 704 or lower, both the new VGC and the ROM upgrade are required.
- when the first three digits of the computer's serial number are 705 through 724 (inclusive), only the new ROM is required.
- when the first three digits of the computer's serial number are 725 or higher, neither of the upgrades is required.

Macintosh II: Electrohome Video Projection Connection

Article Created: 7 November 1988
Article Last Reviewed: 30 June 1992
Article Last Updated:

TOPIC -----

How can I project the display of the Macintosh II Video Card?

DISCUSSION -----

There is a product called the Electrohome RGB 2000H which is used to project the video display of the Macintosh II. The card used in this configuration is the Macintosh II Video Card with full memory (512K of video RAM) for the 8 bit color mode. Two cables are needed: the 15 pin video cable that comes with a Macintosh II color monitor, and the 10 pin cable that comes with the Electrohome projector. An interface is necessary to convert the signals from the Video Card with Macintosh II RGB monitor cable to that of the Electrohome and its cable. Such an interface is provided by Covid, Inc.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Here are their pinouts of Macintosh II monitor and Video Card for reference:

Macintosh: Disk Repair with Copy II Mac

=====

When other means (Fedit+, Disk First Aid) have failed to repair a disk that's gone bad, try this procedure:

1. Copy the disk with the sector copy mode of Copy II. When Copy II Mac encounters a bad block, it zeros that block on the destination disk. This gets rid of any unreadable blocks.
2. Run Disk First Aid v1.2 with "Repair Automatically" (Options menu) checked.

When a disk goes bad, don't be too quick to give it up for lost. There are several ways to recover data from bad disks. Oh, yes -- back up often.

HyperCard 1.0: Tiny Bug in Help Stack

=====

Article Created: 31 August 1987
Article Last Reviewed: 3 June 1992
Article Last Updated:

In the Help stack of HyperCard 1.0, there is a single card with a small bug. It's the card named "Math functions (cont.)".

If you click on the left or right screen button, nothing happens. (You CAN, however, move to the next/previous card by clicking right below one of the buttons or by using the right/left arrow key.)

The problem: the card's text fields partially overlap the arrow buttons at the bottom. (These fields are invisible, so you can't see them if you're browsing.) When you click on the buttons, you click in the text fields instead.

Here's how to repair the card:

1. Put HyperCard into Edit mode.
2. Bring up the "Math Functions (cont)" card.
3. Select the Field mode in the Tools menu (the upper-right box).
When you do this, the text fields become visible, and you'll see the overlap.
4. Click the arrow in the lower parts of the three fields that overlap buttons, and move them up.

Macintosh SE: Don't Start Up From Bernoulli Drive

=====

This article last reviewed: 31 August 1987

If you are using a Macintosh SE with two internal floppy drives and an IOmega Bernoulli drive, be sure to start up the computer with an 800K System disk in one of the drives. If you don't, the computer will try to start up from the Bernoulli drive, and will crash.

In the case of a Macintosh SE with built-in hard disk drive, the computer will always start up from the built-in hard drive.

Macintosh SE: HD-20SC Setup and Parameter RAM

=====

This article last reviewed: 31 August 1987

When you update the SCSI driver on a Macintosh SE, using HD20SC Setup 1.4, the parameter RAM is affected in three ways:

1. It validates the SCSI ID for the internal drive. If it is determined not to be a "reasonable" number, it is set to zero.
2. The time to wait for the internal drive to start up is checked and set, if necessary.
3. There is a byte that is sometimes overwritten if the system crashes. If this happens, the Macintosh won't start up from the SCSI drive. This byte is reset if necessary.

File Formats: Where to obtain TIFF and EPSF Specs (1/95)

=====

Article Created: 1 September 1987
Article Reviewed/Updated: 6 January 1995

TOPIC -----

Where can I get information on the TIFF and EPS file formats?

DISCUSSION -----

The TIFF 6.0 specification is available in the TIFF Developer's Kit. Information on obtaining this kit and joining the Aldus Developer's Association (ADA) may be obtained from the Developer's Desk at Aldus Corporation, or from the following FTP site:

<ftp://sgi.com/graphics/tiff/TIFF6.ps.Z>

The EPSF (Encapsulated PostScript File) format is available from the Technical Specialists Group at Adobe Systems Inc. Additional information can also be found in the PostScript Language Reference Manual, Adobe Systems Inc.

To locate a vendor's address and phone numbers, use the vendor name as the search string.

Apple II Family: Square Wave Power Source (2/97)

=====

Article Created: 01 September 1987
Article Reviewed/Updated: 17 February 1997

TOPIC -----

This article discusses the use of a square wave AC power source, as opposed to the normal sine wave, with the Apple II family of computers.

DISCUSSION -----

The Apple II power supply is of a switching type that rectifies the AC input voltage to a DC voltage for use internal to the supply. The AC input is first sent through a line filter and then to a diode bridge for rectification. The line filter consists of inductors and capacitors to smooth the waveform of the input voltage. This action would soften the square waves an inverter might supply and the whole combination makes it OK to use an Apple II on a square wave AC supply.

Apple File Exchange 1.0.1: Problem Formatting ProDOS Disk On Mac

Revised: 12/3/88
Security: Everyone

Apple File Exchange 1.0.1: Problem Formatting ProDOS Disk On Mac

=====

This article last reviewed: 10 November 1988

Apple File Exchange 1.0.1 (part of System 5.0, MultiFinder release) sometimes fails to correctly format a ProDOS Disk on a Macintosh. This happens when the user first types an invalid name for the new ProDOS disk, then makes a correction to it. Here's the scenario:

1. The user puts the AFE disk in the Macintosh's external drive, and starts the program.
2. User ejects the startup disk from the internal drive, via the appropriate clicks on the Drive and Eject buttons, then replaces it with a blank unformatted disk.
3. AFE tells the user that it can't read the disk, and asks if the user wants to initialize it.
4. User selects 800K, ProDOS format, and clicks Initialize.
5. AFE initializes the disk and asks the user to name it.
6. The user accidentally types a name that is too long for ProDOS (or uses illegal characters).
7. AFE ejects the newly-formatted ProDOS disk and asks for the startup disk back.
8. The user inserts the startup disk, and AFE displays an alert about an invalid ProDOS name.
9. The user clicks OK, and sees a dialog box containing a suggested (valid) name.
10. The user makes minor changes to the name, but keeps it a legal ProDOS name, and click OK, expecting AFE to eject the startup disk and ask for

the newly-formatted ProDOS disk back to record the new name.

Seconds later, the user has a hybrid disk: part Macintosh startup disk, and part ProDOS volume name -- AFE didn't let the user swap disks one last time.

ADB Keyboards: Sharing Among Several Computers

Revised: 9/1/87
Security: Everyone

ADB Keyboards: Sharing Among Several Computers

=====

This article last reviewed: 9/1/87

It is possible for more than one computer (Macintosh SE, Macintosh II, or Apple IIGS) to share an ADB keyboard and the mouse attached to it. Switch the data leads only, not the power switch on the keyboard.

Only one keyboard is hooked up at a time; at power-up, each is assigned the default ADB address of 2. This default gets assigned all the time (unless the software specifies otherwise) and so they all have the same address. Thus, when the computer addresses the keyboard at address 2, whichever keyboard is attached will respond.

The switching should take place when there's no activity, so as not to lose or confuse data.

Remember: don't change the default address with software.

AppleShare: TOPS Compatibility

Revised: 5/11/89
Security: Everyone

AppleShare: TOPS Compatibility

=====

This article last reviewed: 1 November 1988

Overview

AppleShare volumes mounted with the new network Chooser on an AppleShare WORKSTATION Macintosh can be made available (via TOPS on the same Macintosh) to the TOPS network. The AppleShare volume can then be accessed from any TOPS station on the network, including MS-DOS computers.

TOPS allows MS-DOS connectivity to the AppleShare file server. AppleShare volumes mounted on a Macintosh workstation and then published via TOPS are 'available' in a PC TOPS window. The volume can then be mounted by the PC and accessed like any other TOPS volume.

Potential Trouble Spots

TOPS does not recognize AppleShare folder access privileges. Publishing any AppleShare volume via TOPS gives the same access privileges to any TOPS station that might access the volume. This means that if an AppleShare user published a private volume or folder via TOPS, the volume or folder would be available to all other TOPS users on the network. When an AppleShare volume is accessed through any TOPS station, it appears to the AppleShare server that the AppleShare workstation that originally mounted the volume is accessing the server. This extends the access privileges of the original user to all TOPS workstations, effectively bypassing the AppleShare user privileges and restrictions.

Volumes and folders can safely be accessed through AppleShare or through TOPS, but not both. AppleShare uses the Apple AFP file transfer protocols, while Centram uses a proprietary file transfer scheme. An AppleShare volume or folder that has been first mounted by an AppleShare workstation and then published via TOPS should not then be mounted through both AppleShare and TOPS at the same time on another AppleShare workstation. Calling the file or folder will result in the two different file transfer mechanisms clobbering each other.

TOPS should NOT be installed on the AppleShare Server. This could work if ALL volumes were published from the File Server as "Read-Only" volumes, though there is probably no reason to configure any network this way. The reason for this conflict is that AppleShare keeps a copy of the server directory, which would not be properly updated if a server volume were modified by any TOPS users.

AppleShare shows all folders on the mounted volume, irrespective of whether the workstation user has access privileges to the folders. If an AppleShare volume has first been mounted by an AppleShare user, published via TOPS on the Macintosh workstation, then viewed through the TOPS window on any TOPS workstation, all the folders in the volume will be listed. If the volume is mounted via TOPS and private folders are opened with the Finder, the folder's window will be empty. Attempting to mount a private folder via TOPS will cause an error message.

Macintosh: How to Make a Color Startup Screen

Revised: 3/31/93
Security: Everyone

Macintosh: How to Make a Color Startup Screen

=====

Article Created: 1 September 1987

Article Change History

03/12/93 - EXPANDED AND UPDATED

- To take new developments into account.

TOPIC -----

How can I create a color startup screen for my color Macintosh? I'd also like to know if the Performa series supports color startup screens?

DISCUSSION -----

The Macintosh line and the Performa line support startup screens. Color models will display color startup screens if the StartupScreen file contains color information. Startup screens are supported in all versions of the Macintosh and Performa operating systems.

To operate as a startup screen, a document must be in the System folder and be named StartupScreen. Some color graphics application programs, such as Canvas, SuperPaint, and Color MacCheese, have a startup screen option: they let you save a document specifically as a startup screen.

If your graphics application doesn't have that option, here's how to make a color startup screen. In summary, you'll place a PICT resource with ID 0 in the StartupScreen file.

The easiest way to create a PICT resource is to copy a color picture from an application, or from a screen "dump" and paste it into the Scrapbook. Then use ResEdit to find the resource in the Scrapbook File and paste it into the StartupScreen file.

- 1) Copy a color picture to the Clipboard, either with a color graphics

application, or with a screen dump utility.

- 2) Paste the picture into your Scrapbook. (You can quit the graphics application.)
- 3) In ResEdit, copy the picture from the Scrapbook into the resource fork of the file named Startupscreen in your System folder. The picture will be saved as a PICT resource.
- 4) Still in ResEdit, change the ID of the PICT resource to 0 (zero).
- 5) Quit ResEdit and restart your system.

Macintosh II Video Card: Description of Pins and Signals (2/95)

Revised: 2/14/95
Security: Everyone

Macintosh II Video Card: Description of Pins and Signals (2/95)

=====

Article Created: 17 May 1988
Article Reviewed/Updated: 14 February 1995

TOPIC -----

This article answers some of the questions that have arisen about connecting third-party peripherals (monitors, projectors, video recorders) to the Macintosh II video card.

DISCUSSION -----

Only an interface cable need be created for most of the signal compatible monitors and projectors. Some devices will need other signals than those provided by the video port. There is another set on the card that supplies signals not needed by the Apple High Resolution Monitors.

Before a third-party peripheral is connected, it must follow the Macintosh video scheme. It must have:

- a bandwidth of 22 MHz or greater
- a horizontal scan rate of 35 KHz or greater
- an analog RGB video display (for color)
- reception of a TTL negative going sync signal

There are four video signals and four accompanying ground pins on the DB-15 female connector of the Macintosh II video card:

- | | | |
|----|--------------------|--|
| 1 | RED VIDEO GROUND | |
| 2 | RED | (analog) |
| 3 | CSYNC * | (TTL) used by Apple Displays |
| 4 | CSYNC GROUND | |
| 5 | GREEN + CSYNC | (analog) used for Mono; CSYNC unused by Apple displays |
| 6 | GREEN CSYNC GROUND | |
| 9 | BLUE | (analog) |
| 12 | GREEN + CSYNC | (analog) not used |
| 13 | BLUE VIDEO GROUND | |

* This is composite sync (vertical and horizontal)

The Apple High Resolution Monochrome Monitor uses only the green video and the composite sync signal lines: pins 3,4,5, and 6.

The Macintosh II video card can produce RS170 interlaced video signals as well as the usual RS343 non-interlaced. This is a software controlled mode that utilizes a 12.27 MHz clock. The timings for the mode follow the RS170 specifications, giving a video image similar to the Amiga computer's 400- line mode (visible flickering). Monitors with lower scan rates than those required by the RS343 mode can use the RS170 mode at the disadvantage inherent in lower resolution devices. This mode is unsupported at this time, and no drivers are available.

Here is a description of the video signals and their timings:

Horizontal SYNC:

Frequency	35 KHz
Period	$1/35 \text{ KHz} = 28.5714 \text{ microseconds}$
Back Porch	96 dots
Front Porch	64 dots
Sync	64 dots
Active video	640 dots
Blanking	224 dots (back porch + front porch + sync)
Pixel Clock	30.24 MHz (one dot = $1/30.24\text{MHz} = 33.06878\text{ns}$)

Vertical SYNC:

Frequency	66.67 Hz
Back Porch	39 horizontal scan lines
Front Porch	3 lines
Sync	3 lines
Active	480 lines
Total	525 lines = 15 milliseconds

Lines are derived from $1/\text{Scan rate} = 1/35\text{KHz} = 28.5714 \text{ microseconds}$.

Other values:

vertical even field blanked lines	45 lines
video rise and fall times approx.	5-6 ns
video signal black level	0 volts
video signal green+csync black level	0.3 volts
video signal white level	1 volt

When tested at the connector, because the 75ohm terminating resistor within the monitor is not loading the line, the signals will appear to range from 0-3 volts.

The above signals are for the non-interlaced RS343 standard video used by the Apple High Resolution video monitors. Note that while the video signal voltage levels comply with the RS343 standard, the CSYNC does not as it is a TTL signal.

Although not present on the external video connector, there are also six more video signals available on connector space J3 on the video card. J3 is a set of 14 holes located along the top of the video card and between the TFB and the video port edge of the board (sometimes covered by the serial number label).

J3 signals:

- 1 GROUND
- 2 GROUND
- 3 GROUND
- 4 EXT_PBCLK (EXTERNAL PIXEL BUS CLOCK)
- 5 GROUND
- 6 CLK_SEL (PIXEL BUS CLOCK SELECT)
- 8 CBLANK~ (COMPOSITE BLANKING SIGNAL)
- 9 GROUND
- 10 VSYNC~ (VERTICAL SYNC)
- 11 GROUND
- 12 HSYNC~ (HORIZONTAL SYNC)
- 13 VCC
- 14 CLK_SEL~ (PIXEL BUS CLOCK SELECT)

Pins 1,2,3,5,7,9,11 are tied to ground

1) Pin 4 is EXT-PBCLK. This is a tristateable clock that can be driven from a master card onto the Mac II video card. It must be tristated except when the video merge card or whatever is attached to the Mac II video card is trying to drive the video with its own pixel clock.

2) Pin 6 is CLKSEL. This is an active high pin that indicates that the master card wishes to drive the pixel clock line. This pin should be driven high only when pin 14 is driven low and the interlace bit is set on the Macintosh II video card. Eventually a call will be supported which will set the interlace bit in the Macintosh II video card.

3) Pin 8 is CBLANK~. This is the composite blanking signal for the video being driven by the Mac II video card.

4) Pin 10 is VSYNC~. This is the vertical sync signal for the video being generated by the Mac II video card. This signal is bidirectional and can be driven by a master to allow for genlock. The direction of this signal is under software control. A call will soon be supported to allow for setting up the card for genlock.

5) Pin 12 is HSYNC~. This is the horizontal sync signal for the video being generated by the Mac II video card. This signal is bidirectional and can be driven by a master to allow for genlock. The direction of this signal is under software control. A call will soon be supported to allow for setting up the card for genlock.

6) Pin 13 is VCC. No more than 100mA may be drawn from this VCC pin.

7) Pin 14 is CLKSEL~. It is an inverted version of pin 6.

Some video units require a separate horizontal and vertical sync. These can be obtained through the signals supplied on J3.

Making a video cable: use a cable with an impedance of 75 ohm, like RG59, particularly for long distances (over 12 feet). As for the pin considerations for the connectors, pay attention be paid to grounding each video line as well as the shield to its appropriate pin on the video device and card. To keep within RFI levels, ferrite rings or beads can be attached.

SCSI Terminators: Using them with a Macintosh and a SCSI Drive

=====

This article last reviewed: 9/1/87

This is to clarify when to use terminators when connecting a Macintosh II or Mac SE to a SCSI drive. The information on EXTERNAL drives applies to the Macintosh Plus as well.

Mac II or Mac SE with 40MB Internal Drive

The internal 40MB drive itself is automatically terminated. When connecting external SCSI devices, you need a terminator at the end of the chain.

- Mac II/SE + internal 40MB
no terminator necessary
- Mac II/SE + internal 40MB + external SCSI
terminator at external SCSI
- Mac II/SE + internal 40MB + external SCSI ... external SCSI
terminator at end of chain

Mac II or Mac SE without 40MB Internal Drive

There must be at least one terminator between the Mac II/SE and the first SCSI device, and one more at the end of the line if there is more than one SCSI device.

- Mac II/SE + external SCSI
terminator at external SCSI
- Mac II/SE + external SCSI ... external SCSI
terminator at beginning and end of chain

Again, the information on external drives applies to the Macintosh Plus

as well.

Macintosh II: Sharing Monitors & Keyboards

Revised: 7/2/92
Security: Everyone

Macintosh II: Sharing Monitors & Keyboards

=====
Article Created: 1 September 1987
Article Last Reviewed: 25 June 1992
Article Last Updated:

TOPIC -----

There is no way for several Macintosh II computers to share both a single keyboard and a single monitor. A switch for a monitor should be relatively easy to make, since you are only supplying the monitor with a stream of bits. A switch for the keyboard is more difficult, because you must deal with the Apple Desktop bus (ADB).

DISCUSSION -----

The first time a keyboard is recognized, it receives an ID number from the computer and retains this ID number. When the multiple computers started up, one after the other, they would all get the same Keyboard ID. The problem is that when the keyboard is subsequently addressed, it assumes it is communicating with just one computer and forgets its ID number. So when a second computer attempts to communicate with it, nothing happens.

Conceivably, you could implement a program that echoed all the keyboard information out from one "master" Macintosh II, over AppleTalk, but still you would have to rewrite quite a bit of lower level code.

LaserWriter: How to Tell What ROM is Installed

=====

This article last reviewed: 1 September 1987

A customer reports that his LaserWriter stops printing in the middle of a job, with a message that it is unable to print or set up a spool file.

This could be caused by using a LaserWriter with version 1.0 ROM, which had an XOFF-XON problem (an XOFF was sent by never an XON). This resulted in the LaserWriter not finishing its printing. The 2.0 version LaserWriter ROM corrects the problem.

Here's how to tell what version ROM is in your LaserWriter:

1. Look at the test sheet that comes out of the LaserWriter when it's started up.
2. On the test sheet, find the picture of a page with a graph.
3. The ROM version is shown in the lower-left corner of that picture.
4. If the number is 1.0, replace the LaserWriter ROM with the latest version.

AppleShare, LaserShare, InterMail: All From One Server

=====

This article last reviewed: 1 September 1987

It is possible to use the same hard disk for AppleShare, LaserShare, and InterMail. One Macintosh Plus, Macintosh SE, or Macintosh II with server can then do triple duty: file, printer, and mail service.

1. Copy InterMail's server icon into the AppleShare server folder.

On first launch, loading before AppleShare, InterMail creates its own data file, which disrupts AppleShare's launch. We'll take of that in a moment.

2. Start up the Server Installer.
3. Drag the InterMail data file into the Server folder.
4. Run AppleShare's Admin application, which 'repairs' the server desktop.
5. Restart. InterMail and AppleShare will run properly.
6. While installing LaserShare according to the directions, enable it as a 'Concurrent Application.'
7. Restart again. All three applications will load and run.

Since InterMail loads first, and in the background, its memory is reserved before AppleShare and LaserShare launch.

-	5	Eschatology 2	6144	150224
-	-	(not used)	1	156368

The number in the 'slice' column is the number used in the A/UX disk specification of the form /dev/dsk/c3d0s0. The slice number is the one following the "c"--"3" in this example. A disk slice is a region of a disk accessible from the CPU. The partition number is the one used in the partition map (you don't need to know much about this one). The partition name is how some commands (such as pname) refer to the partition.

The number in the 'size' column is the size of the partition in 512-byte blocks.

The number in the 'start' column is the number of the first block in the partition (again in 512-byte blocks).

The two partitions 'root' and 'mac' are the two most used. The 'root' partition is the one that A/UX runs from, and the 'mac' partition is the one that the system boots from (in SASH). The swap partition is used by the A/UX system to swap programs out to.

The two Eschatology partitions are copies of each other. They are used with the esch program (available from SASH) to help recover the root file system in case of a crash. They are located at opposite ends of the disk, so a

physical head crash will probably leave one of them intact.

This information was provided by Apple Software Configuration Management.

Apple IIGS: Using ToolBox To Create/Modify Character Sets

=====

This article last reviewed: 19 January 1988

The Apple IIGS ToolBox allows programmers to do some interesting things. You can, for example, redefine the keyboard layout by patching certain calls to the ToolBox.

To create new character sets, you'll intercept the data coming from the keyboard, translate it to whatever you want, and store it in the proper place.

To learn how to do this, you'll need the Apple IIGS ToolBox Reference Manual (two volumes, APDA order number K2BGST). This book describes the ADB toolset that you would use to alter the keycodes. The Keyboard Micro gets data from the ADB keyboard, then software is called to get that data and send it to the \$C000 area. Your software would read the keyboard micro, and then translate the keycode that it gets back into an ASCII (or whatever) type of code, storing it back into the \$C000 vector.

Altering the character set is not possible in text mode, because the character sets are in ROM (in the VGC custom IC) and can't be changed. But there is a simple way to accomplish this: use the standard graphics environment that the Apple IIGS provides. By using the Font Manager, you can create your own customized fonts for any language and any type of symbols. This system is also documented in the Apple IIGS ToolBox Reference Manual.

Space Quest: It is Incompatible with Old Apple IIGS ROMs

=====

This article last reviewed: 11 January 1988

A software package called Space Quest, part of the Endless Disk Drive, can produce a Fatal System Error -> 0814 unless the following rules are observed:

- An Apple IIGS with serial number E704 or less needs to have both the VGC and ROM upgrades.
- An Apple IIGS with serial numbers E704 - E723 needs the ROM upgrade only.
- You must use System 2.0 or later. This means that Space Quest will not run with the old Apple IIGS ROMs (342-0077-A).

MIDI: General Description and Overview (1/95)

Revised: 1/19/95
Security: Everyone

MIDI: General Description and Overview (1/95)

Article Created: 8 February 1988
Article Reviewed/Updated: 19 January 1995

TOPIC -----

This article contains a description of MIDI (Musical Instrument Digital Interface), and how it is used on the Macintosh.

DISCUSSION -----

Introduction

MIDI is a communications protocol --
a standard way of exchanging information:

- between electronic musical instruments, and
- between computers and those instruments.

By connecting the Apple MIDI interface to your Macintosh or Apple IIGS, and using MIDI software and instruments designed for the purpose, you can use your computer to compose, edit, orchestrate, and control playback of music on MIDI instruments such as keyboard synthesizers, drum synthesizers, and tone generators. You can then use your computer and MIDI software to transcribe the music into musical notation that can be edited, saved on a disk, and printed.

The most common use of a computer/MIDI setup is to record songs which can be saved onto the computer's hard disk, much like using a tape recorder to record songs. Advantages of using a computer/MIDI setup are:

- You can easily edit what you played on your instrument without having to re-play it. You can change the timing, duration, pitch, and volume of individual notes or whole passages.
- You can record several different tracks, one at a time, to make a complete song, without having to use a multi-track tape recorder.

- For difficult passages, you can play your instrument slowly, and have the computer increase the tempo.
- The computer can cue to any song or any part within a song much faster than a tape recorder can.
- You can record different tracks of a song, and then practice playing along with those parts, as though you were playing with other musicians. (You can do this with a tape recorder, but it's much more cumbersome.)
- You can record one or more tracks of a song, and play along with those parts during a live performance. This is handy if you want to be a solo musician, or if you are missing band members.
- Unlike cassette tapes, the quality of a digital computer recording will not deteriorate over time.

Recording music with MIDI instruments such as keyboards, drum machines, and sound modules is easy. MIDI translators are available for electric guitars, but they are an added expense. Although computers can make digital recordings of analog instruments such as voice and horns in addition to recording MIDI instruments, this requires expensive computer hardware and storage devices.

Typical MIDI Setup

Serial Cable

Every desktop Macintosh manufactured since 1986 comes with two standard DIN-8 serial ports. You connect the Macintosh to a MIDI interface (a small box) with a standard serial cable--the same kind used to connect the Macintosh to a StyleWriter printer. It does not matter which end of the cable is used in either device.

MIDI Interface

Most MIDI-equipped instruments contain both a receiver and transmitter. However, some instruments may have only a receiver or transmitter. The receiver accepts messages in a MIDI data format and executes the MIDI commands. The transmitter originates messages in MIDI data format, and transmits them by way of a line driver and UART. The MIDI interface consists of an optoisolator, UART (Universal Asynchronous Receiver-Transmitter), and other interface function hardware. The MIDI interface has at least one MIDI IN jack and MIDI OUT socket.

A MIDI interface operates at 31.25 Kbaud (+/- 1%) asynchronously, using a data format of one start bit, eight data bits, and one stop bit. This makes a total of 10 bits for each 320 microsecond period per serial byte.

The MIDI circuit is designed to accommodate a 1.5 mA current loop with a

logical 0 as current ON. Also, one Output can drive one Input, and ONLY one, with a rise and fall time of less than 2 microseconds.

As specified by the IMA (International MIDI Association), MIDI connectors are DIN 5 (180 degree) female receptacles. The MIDI connectors are labelled MIDI IN and MIDI OUT, with pins 1 and 3 left disconnected in both the transmitter and receiver.

MIDI cables may be a maximum of fifty feet (15 meters,) with shielding connected to pin 2 at both ends.

MIDI Setup

The MIDI OUT of the interface is connected to the MIDI IN of an instrument, and the MIDI OUT of the instrument is connected to the MIDI IN of the interface. These connections are made with standard MIDI cables.

TO RECORD MUSIC FROM A MIDI INSTRUMENT

TO PLAY BACK MUSIC THAT IS STORED IN THE COMPUTER

MIDI Instruments

A MIDI instrument is an electronic instrument which can send and receive MIDI information. Common MIDI instruments include keyboards, drum machines, and sound modules (also called tone generators). A MIDI instrument can be connected to a MIDI interface, which is in turn connected to a computer. Some MIDI instruments have a built-in MIDI interface.

A sound module, also called a tone generator, is like an electronic keyboard without the keyboard keys. It is a device containing all the sounds a keyboard would contain, and these sounds can be triggered by another MIDI keyboard, or by a computer using sequencing software.

MIDI Data Format

Except for the "Real-Time" and "Exclusive" messages, all MIDI communications are transacted through multi-byte "messages" of one Status byte followed by one or two Data bytes. The messages are divided into two main categories:

1. Channel
 - Voice
 - Mode
2. System
 - Common
 - Real-Time
 - Exclusive

$$[\text{Status}] \text{ ----- } + \text{ ----- } [\text{Channel}] \text{ ----- } \text{ or } \text{ ----- } [\text{System}]$$
$$+ \qquad \qquad \qquad +$$
$$[\text{Voice or Mode}] \qquad \qquad [\text{Common, Real-Time, or Exclusive}]$$

Status Byte

The Status byte is an eight-bit binary number with the most significant bit set (1). The purpose of the Status byte is to identify the message type for the Data bytes.

Except for Real-Time messages, a new Status byte always commands the receiver to adopt the new status, even if the receiver has not yet completed the previous message.

Channel Messages

The Channel message is identified by a four-bit number in the Status byte which address the message to one of the sixteen channels. In this way, messages are sent to any units in the system whose channel number matches the channel number encoded in the Status byte.

- Voice: A type of Channel message used for controlling an instrument's voice.
- Mode: A type of Channel message used for controlling an instrument response to a voice message.

System Messages

The System message does NOT have a channel number encoded and the message is intended for all units on the system.

- Common: The Common message is intended for all units in the system.
- Real-Time: The Real-Time message is intended for all units in the system and may be sent at any time, even between messages of a

different status type. A Real-Time message is either acted upon or ignored by the unit, after which the receiving unit will resume process under its previous status.

- Exclusive: The Exclusive message may contain any number of Data bytes and will include a Manufacturer's Identification (ID) code. All but the unit whose receiver recognizes the ID code should ignore the Data bytes.

COMPUTER

You need "music processing software" to enter and edit music, just like you need word processing software to enter and edit text. Music processing software is commonly referred to as "sequencing software".

If you would like to know more about MIDI, a number of helpful books are available from bookstores.

Security: Everyone

System 4.1: Text Spacing Problems When Using A LaserWriter

=====

Article Created: 8 February 1988
Article Last Reviewed: 5 November 1991
Article Last Updated: 18 October 1988

TOPIC -----

This article describes text spacing issues with System Software version 4.1.

DISCUSSION -----

Using System 4.1 and LaserWriter or LaserWriter Plus, you may experience text spacing problems, either with screen fonts or text fonts, or with both.

- A problem in the System 4.1 software occasionally corrupts the Fond resource, causing a font to space incorrectly. To correct the Fond resource, remove the offending fonts (all sizes) using Font D/A Mover 3.6, and reinstall them. This action will force the font table in the Fond resource to be recreated, which will correct the problem.
- Also, under the Print option in Microsoft Word 3.01, there is a selection for printing WITH or WITHOUT fractional widths. This option defaults to WITHOUT (not using fractional widths,) and must be selected to obtain correct spacing with LaserWriter fonts.

LaserWriter: Why It Prints Only Two Pages When Using MS-DOS

=====

This article last reviewed: 18 January 1988

If you are printing to a Laserwriter from an MS-DOS machine, and can't print documents more than two pages long (for instance, a ten-page document can only be printed as 5 two-page documents,) it is most likely a "handshaking" problem.

The MS-DOS system and the LaserWriter are not set up for the same kind of handshaking, and the printout is only one buffer-length long.

Make sure that both the printer and the MS-DOS system are set for either DTR or Xon/Xoff handshaking.

Where to Find Info on the PICT File Format

=====

This article last reviewed: 11 January 1988

You can find information on writing graphics files in PICT format in:
Macintosh Technical note #27.

This Technical Note is in the Developer Service bulletin board. Open the
following folders in order:

1. Developer Technical Support
2. Macintosh
3. Technical Notes
4. 26-50

Apple wants Technical Notes to be distributed as widely as possible. The
file may be downloaded for dealers who don't have access to the Developer
Technical Support bulletin board. Technical Notes are sent to all certified
developers at no charge. There are no restrictions on copying Technical
Notes, except that they must not be resold.

APDA also supplies this and other Technical Notes on both disk and paper.

Apple IIGS System 3.1: How to Make It Come Up Into The Launcher

=====

This article last reviewed: 11 January 1988

To get the Apple IIGS System Disk version 3.1 to come up into the Launcher, rather than in the Desktop:

1. Open the SYSTEM folder.
2. Rename START to STARTOLD.
3. Rename LAUNCHER to START.

Under ProDos 16, the file named START runs before any of the .SYSTEM files can execute. The Apple IIGS will now start up and run the new START file first, skipping the IIGS Finder.

AppleTalk ImageWriters: Why They Switch Jobs Back and Forth

Revised: 8/21/89
Security: Everyone

AppleTalk ImageWriters: Why They Switch Jobs Back and Forth

=====

This article last reviewed: 11 January 1988

Two or more AppleTalk ImageWriter users printing at the same time may find that the ImageWriter "interleaves" the pages, switching between jobs. In other words, the ImageWriter prints page 1 from the first document, then page 1 from the second document, followed by page 2 from the first document, page 2 from the second document, and so on.

The problem is caused because the application in use works by the "spool-a-page / print-a-page" method of printing: the application prints each page of a document as a separate job instead of calling PrPicFile to print the entire picture file. Many applications adopted this method of printing to avoid running out of disk space while the ImageWriter driver was spooling the document to disk. Because printing code is moved from application to application, this method is still in use.

Applications that use the method of printing described in "Inside Macintosh" (ISBN 0-2-1-17737-4), Volume II, page 155, will print by job, and will not interleaf. This method allows the multiple bin option of the ImageWriter LQ to work correctly.

Short of asking the designers, the only method of testing which method a given application uses is by testing it on multiple printing jobs.

Node Check: Not Designed For Use With EtherNet

=====

Article Created: 13 January 1988
Article Last Reviewed: 7 August 1992
Article Last Updated: 7 August 1992

TOPIC -----

I have tried to use Node Check (formerly called NetCheck) with EtherNet and have gotten confusing results.

DISCUSSION -----

(NetCheck's name was changed for legal reasons, and the function of the program did not change, though some slight fixes were incorporated into Node Check 1.0. For reference, NetCheck 1.0 was released 1/28/85, 2.0 was released 9/9/85, and Node Check 1.0 was released 2/18/87.)

Node Check was NOT designed to work with EtherNet. EtherNet uses a 48-bit address scheme that is assigned on a static basis, and AppleTalk uses an 8-bit address scheme, dynamically assigned. Furthermore, standard EtherNet does not use address names.

The current version of Node Check is 1.0 and will not be updated in the future.

AARP (Apple Address Resolution Protocol) is designed to handle addressing differences. The address and name information available to a given network is based on the developer's implementation of AARP.

Article Last Updated: 30 June 1992

TOPIC -----

Is there some way I can lock only ADB devices such as the keyboard and mouse?

DISCUSSION -----

There is currently no application or desk accessory available that locks only ADB devices. The security utilities that are available either lock access to a disk or folder, or disable the drive at system power-down.

The Quadra 900 and Quadra 950 provide a keyswitch which can lock out ADB devices. Currently, they are the only Macintosh computers with this feature.

LaserWriter Driver 5.0: Print Problems with a Mac 512Ke & Plus

=====

Article Created: 8 February 1988
Article Last Reviewed: 31 October 1991
Article Last Updated: 18 October 1988

TOPIC -----

This article describes issues when using LaserWriter Driver and LaserWriter Pre version 5.0 on a Macintosh 512Ke or a Macintosh Plus.

DISCUSSION -----

If you are running LaserWriter Driver (and Prep) 5.0 on Macintosh 512Ke or Macintosh Plus, you may experience a problem with documents containing Bit-Mapped Graphics: the LaserWriter prints the document, then the Macintosh returns to the application, hangs, and must be restarted.

The problem is due to incompatibility between the driver file and the System and Finder files. The solution is to use a previous version of the LaserWriter Driver and LaserWriter Prep files, such as version 4.0, or move up to a more current version of the LaserWriter drivers, such as 5.2, 6.0, or 7.0 for the Macintosh Plus.

AppleShare 1.1: Problems Running It With InBox

=====
Article Created: 8 February 1988
Article Last Reviewed: 6 April 1992
Article Last Updated: 6 April 1992

TOPIC -----

The following discusses problems with running AppleShare 1.1 with InBox.

DISCUSSION -----

You may have had problems running AppleShare 1.1 and InBox on the same machine and at the same time, with InBox as a background application.

This is because AppleShare 1.1 automatically configures the RAM Cache for optimal use, leaving too little memory for the next application -- the InBox background message center.

One solution is to run the AppleShare 1.1 server in the background, and the InBox message center in the foreground:

When you configure the InBox message center, you have two options: BACKGROUND or DEDICATED. Choose DEDICATED; then AppleShare will start up first in the background, followed by the InBox message center in the foreground.

ImageWriter I & II: Same Documents Print Differently (9/95)

=====

Article Created: 8 February 1988
Article Reviewed/Updated: 19 September 1995

TOPIC -----

Why do the ImageWriter I and ImageWriter II sometimes produce differing results, even though both are working from the same document?

DISCUSSION -----

The following are some possible reasons this could happen:

- Screen fonts print differently with different system versions. Use the font and ImageWriter driver that best suits your needs.
- MacDraw or MacPaint documents that print perfectly on ImageWriter I may show a horizontal white line when printed on ImageWriter II. This is because ImageWriter II has smaller print head wires, which allow the ImageWriter II to produce a finer text quality. The white line is caused by the finer dots failing to overlap. This can be fixed by printing in BEST mode.

LaserWriter: Printing to It With DECserver

=====

This article last reviewed: 13 January 1988

You can use DECserver to print with Macintosh and LaserWriter:

Wire the Macintosh modem port into the DECserver and hang the LaserWriter off the same server, but a different port. Use the Async LaserWriter with the Direct.ACL file.

- Set the various parameters of the server (name, baud rate, XON, etc.) to correspond to the LaserWriter.
- Start up Mac240 on the Macintosh, log in and choose 'C LaserWriter'. Quit Mac240.
- Start up PageMaker. From the Choose Print option under the File menu, select the Apple Driver to be used through the modem port.

NOTE: Only one user can have access to the port while this process is in effect.

- Select Async LaserWriter from the Chooser.

ImageWriter LQ Fonts: How They Compare To LaserWriter Fonts

Revised: 11/22/91
Security: Everyone

ImageWriter LQ Fonts: How They Compare To LaserWriter Fonts

=====

This article last reviewed: 18 January 1988

The ImageWriter LQ comes with its own versions of the Helvetica, Times, Courier, and Symbol fonts. Some of the "LaserWriter" sizes of these fonts have different resource sizes than those shipped with LaserWriters. In addition, the LaserWriter and ImageWriter LQ FONDS for these fonts differ. This has led to questions from some users:

- What are the differences?

The ImageWriter LQ fonts are up to 72 points in size; their spacing and font metrics are essentially identical to the LaserWriters' fonts. The difference in font resource sizes between LaserWriter and ImageWriter LQ is about six bytes.

- What is the correct font installation procedure for machines that will be printing to both printers?

Use the Font/DA mover to move the fonts you wish to use.

(NOTE: You must have a screen font three times larger than the size you are printing installed in the system.)

- Will there be any change in spacing on documents created for the LaserWriter when these documents are printed after installing the ImageWriter LQ versions of the fonts?

There should be NO size differences in the documents (spacing, etc.) between the two fonts -- the screen fonts are fundamentally the same. The only difference should show up in the actual printout because of the differences in resolution (300 dpi vs. 216 dpi,) not because of any font differences.

Remember, the fonts you install are SCREEN fonts, not the actual font used for printing on the LaserWriter, which come from the font metrics information

stored in the printer.

Macintosh II and SE: A List Of Trap Words

=====

This article last reviewed: 15 January 1988

The following is an excerpt from Inside Macintosh, Volume V Appendix C (the 8/17/87 Final APDA draft, the version that APDA is currently shipping).

This appendix lists the trap macros for the new Toolbox and Operating System routines and their corresponding trap word values in hexadecimal. The NAME column gives the trap macro name (without its initial underscore character). In those cases where the name of the equivalent Pascal call is different, the Pascal name appears indented under the main entry. The routines in Macintosh packages are listed under the macros they invoke after pushing a routine sector onto the stack; the routine selector follows the Pascal routine name in parentheses.

NOTE: Traps that aren't currently used by the system are reserved for future use.

Macintosh System 4.2: Problems Displaying Text

=====

This article last reviewed: 14 January 1988

Some Macintosh users who have updated from System 4.1 to 4.2 have discovered problems with their screen fonts -- for instance, certain letter pairs occurring too close together, causing some difficulty reading the characters.

There is a problem with the new system software which may on occasion corrupt the Fond resource. To correct the offending Fond resource, the user will need to remove the offending fonts (all sizes) using Font D/A Mover 3.6, and reinstall them. This action will force the font table in the Fond resource to be recreated, correcting the problem.

Also, in Microsoft Word 3.01, under the Print option, there is a selection for either printing with or without fractional widths. The option default is for NOT using fractional widths, and must be selected to obtain correct spacing with LaserWriter fonts.

LaserWriter: Sending It PostScript Files From VAX

=====

Article Created: 12 January 1988
Article Last Reviewed: 15 July 1992
Article Last Updated: 15 July 1992

TOPIC -----

How can I print PostScript files to a LaserWriter directly from a VAX?

DISCUSSION -----

You can connect a Laserwriter to the RS232 backplane of a VAX and send VAX PostScript files to the printer as long as the files sent are written, saved, and sent as full PostScript files.

To be considered a full PostScript file, the LaserPrep header MUST be present in the PostScript text file. If, for instance, you create a PostScript text file on a Macintosh, and store the file on a VAX to print later, the Laser Prep header must also be included when you actually print that file.

Under System 7, choosing "PostScript File" in the Destination option of the Print dialog box automatically includes the LaserPrep header (in fact, the only way to exclude the header under System 7 is by using the shareware utility Trimmer, which can strip off the header).

Under System 6, the same result is achieved by holding down Command-K immediately after clicking Okay in the Print dialog box.

Macintosh Plus, SE: Modifying Screen Refresh Rate For NTSC Video

Article Created: 10 November 1988
Article Last Reviewed: 24 July 1992
Article Last Updated:

TOPIC -----

Some Macintosh users have wondered about shooting a television picture of the screen of a Macintosh SE or Macintosh Plus: Why does video-camera footage of the Macintosh result in a rolling bar across the image of the computer screen? Can anything be done to solve the problem? And if so, will the Macintosh run correctly after that?

DISCUSSION -----

The "rolling bar" results from the Macintosh SE or Macintosh Plus computer's refresh rate (vertical scan rate) of 60.15 Hz, when television's refresh (vertical scan) rate is 59.94 Hz.

You can use an external or internal clock at 15.612515 MHz (.35% of the Macintosh's internal clock) to stabilize the scan line that rolls down the screen. There are three problems with this:

- Such adjustments void the computer's warranty.
- Ordering a specific oscillator usually takes anywhere from 8 to 12 weeks.
- Once stabilized, the visible scan line will remain visible on the screen.

You might be able to start it within the retrace period (where it rolls off bottom and begins on the top), but the odds are against it.

After the adjustments discussed above, the Macintosh would not be running correctly -- at least in a technical sense. The screen refresh rate would be incorrect, and other Macintosh components dependent on the internal clock would be slowed down accordingly. There are many possible problems,

but applications would probably continue to function without anyone noticing any real problems for some time.

Macintosh: Connecting AppleTalk To A TCP/IP Network

=====

This article last reviewed: 19 January 1988

If you are running on a TCP/IP network, and wish to upload or download files to a Macintosh (and possibly make changes to downloaded files,) MacIP can be used as a stand-alone system or across an AppleTalk network.

MacIP is an IP implementation of the Telnet and FTP communications programs developed at Stanford University, and is provided free from Kinetics with their Kinetics FastPath products.

FastPaths work with the Kinetics driver software to route normal AppleTalk communications onto Ethernet networks -- or, by using MacIP, to communicate in a limited fashion with systems across TCP/IP networks.

For more information, search under: Kinetics

Macintosh II: Comparison of Internal Synthesizers (10/94)

Article Created: 14 January 1988
Article Reviewed/Updated: 10 October 1994

TOPIC -----

Are the sound synthesizers in the Macintosh II the same as those used in the music industry?

DISCUSSION -----

It's important to distinguish between the "synthesizers" built into the Macintosh II, and the "synthesizer" and "sampler" instruments used in the music industry.

In the music industry, the term synthesizer comes from the central components that synthesize or process the sounds they generate -- just as computers are sometimes called CPUs for the main component of a computer. The music industry digital instruments "synthesize" sound from digital information. These instruments store and manipulate digital information and are far more complex in their sound production than are the components built into the Macintosh II.

In the music industry, a sampler is a type of digitizer that converts analog sound to digital information. Samplers derive their name from the discrete samples of analog sound that are converted at high frequencies (usually 44.56KHz) to digital information. This, like music synthesis, is possible on the Macintosh II with third-party solutions. When attempting to produce digitally sampled or generated sound on the Macintosh II, remember that the possible output may be limited by your third-party hardware and software.

The Macintosh II doesn't have hardware comparable to that found in music instruments. The methods of modifying and manipulating the digitized sounds of a music synthesizer are not in the synthesizer logic chips found in the Macintosh II, but in the design of the instrument components. The Macintosh may emulate these products through software and hardware, but is not designed to BE one of them.

Answers to some frequently-asked questions:

- What is the high and low sampling frequency, and can it be changed?

The pre-recorded or computer-generated sounds may be played through the sampled sound synthesizer from 1Hz to 44KHz samples per second. The number of samples per second can be adjusted. The effect of this adjusting is an increase or decrease in pitch.

- What is the maximum sampling length?

Maximum sampling width is 8 bits. However, maximum length of sampled sound that can be PLAYED is restricted only by disk space. This is because sound buffers can be allocated and linked end to end. As sound buffers are played, new data can be loaded from the disk, provided that each buffer is at least 256 bytes long and the load routines are programmed efficiently.

- What method does the Wave Table Synthesizer use?

The methods of wave synthesis listed here are for adjusting or editing wave forms. The wave table synthesizer merely takes a defined sound and plays it. What method is used for creating or modifying the wave is up to the software. Each of the above listed methods can be created in the software that delivers the final wave form to the wave table synthesizer.

- Do all four voices of the ASC wave-table synthesis play in stereo?

Yes, however the note synthesizer does not have the command for stereo sound built into it and therefore is excluded from its use.

Two more notes:

- There is NO sampling capability of the digitizing type built into the Macintosh hardware: the sampled sound digitizer plays pre-digitized sound.
- There are no sound editing capabilities built into the Macintosh hardware.

LaserWriter and LaserWriter Plus: Font Substitution List

=====

This article last reviewed: 18 January 1988

You can find a complete list of the substitution fonts (the exchanges made when Font Substitution is selected) for LaserWriter and LaserWriter Plus on page 51 of the LaserWriter and LaserWriter Plus manual (Engineering Part #030-1296-C.)

The substitutions are as follows:

- NEW YORK changes to TIMES (in LaserWriter and LaserWriter Plus)
- GENEVA changes to HELVETICA
- MONACO changes to COURIER
- SEATTLE, (the font used in Microsoft Multiplan,) changes to a modified version of HELVETICA.

These are the only fonts that have LaserWriter font-substitution. Other fonts are printed as bitmaps.

You can incorporate graphic elements -- boldface and centered text, graphs, pictures, etc. -- into TeachText 1.1 documents. These are "PICT resources", and may be inserted into a TeachText document as follows:

1. Create your document, leaving five carriage returns in the places where you want to place the graphics or specially-formatted text.
2. Create your specially-formatted text or graphics and paste them into the Scrapbook.

NOTE: The text will need to be in "PICT" format. You can use MacDraw to do this.

3. Use a file editor such as FEdit to open your TeachText file to its data fork. Search for the five carriage returns (carriage return = \$0D) and replace the third "0D" with "CA" and write the change to disk. Do this for all places you want to insert the specially-formatted text or graphics.
4. Using ResEdit, open your TeachText document. Select New from the File menu; type PICT in the dialog box, and press Return.
5. Select New again and paste your formatted text or graphics from the Scrapbook into the resource. When done, select Get Info -- for ID type in "1000". Do the same for all the formatted text or graphics in the Scrapbook, remembering to increment the ID by 1 for each successive resource (1001, 1002, etc.).
6. Quit ResEdit, saving changes.
7. Open your TeachText document. Insert or delete carriage returns to adjust

the graphics and formatted text, which will be automatically centered.

Macintosh: How To Change TeachText From Read-Write To Read Only

=====

Article Created: 19 January 1988
Article Last Reviewed: 29 July 1992
Article Last Updated: 10 July 1991

The only way to change a user-created TeachText 1.1 (as well as TeachText 7.0) document from "Read-Write" to "Read Only" is by using a file editor (such as FEdit, or Norton Utilities) to change the file type from "TEXT" to "ttro".

The file creator type must remain "ttxx".

Apple MIDI Interface: Specifications

Revised: 5/26/88
Security: Everyone

Apple MIDI Interface: Specifications

=====

This article last reviewed: 20 January 1988

These are the specifications for the Apple MIDI interface:

Size

- Depth 1.31 in. approx.
- Width 2.08 in. approx.
- Length 2.92 in. approx.

Connectors and cables

Port	Connector	Cable Length
MIDI In	DIN 5	2 meters
MIDI Out	DIN 5	2 meters
Serial	Mini Circular 8	46 cm

MIDI DIN 5 Pinouts

Connector	Pin #	Description
MIDI IN	1	No Connect
MIDI IN	2	Shield Ground
MIDI IN	3	No Connect
MIDI IN	4	Interface Enable
MIDI IN	5	Data In
MIDI OUT	1	No Connect
MIDI OUT	2	Shield Ground
MIDI OUT	3	No Connect
MIDI OUT	4	+5 Volts
MIDI OUT	5	Data Out

..TIL02474-Apple_MIDI_Interface-Specifications.pdf

NOTE: The Apple MIDI interface does not support MIDI THRU. However, a MIDI musical instrument may have a MIDI THRU port which can be used.

Power

The Apple MIDI interface requires no external power supply or power cable. Power for the Apple MIDI interface is supplied through the serial port from the system.

Connecting the Apple MIDI Interface to a Computer

The Apple MIDI interface may be connected to either the PRINTER or MODEM ports of the Macintosh or Apple IIGS. However, depending on the software used, it may be necessary to use only one of the two ports. Consult the current software manual for the proper port selection.

To connect one MIDI device to your computer:

- Run one MIDI cable from the IN port on the MIDI interface to the OUT port on the MIDI device
- Connect the other MIDI cable from the MIDI Out port of the MIDI interface to the In port of the MIDI device.
- WITH THE COMPUTER TURNED OFF, connect one end of the mini circular-8 cable to the computer and the other end to the Apple MIDI interface. When the MIDI interface is being used with the Apple IIGS it may also be necessary to reconfigure some parameters in the systems control panel.

To connect two MIDI devices to your computer:

- Connect the first device (the one with a keyboard) as in the directions above for one device.
- Run a third cable from the Thru port on the first MIDI device to the In port on the second MIDI device.

To connect a third (or more) MIDI device:

- Run a fourth cable from the THRU port on the second device to the IN port on the third MIDI device.
- This process can be continued with a cable from the third MIDI device to the IN port on the fourth MIDI device, and so on, as you continue to string MIDI interfaces.

NOTE: Only the FIRST device, the one with an outbound line back to the computer, can send information back to the computer. The other devices can only respond to signals generated by the computer, or by the first device as relayed by the computer. Some MIDI software has a keyboard select feature or a command for PATCH THROUGH which lets you send signals generated from the first device to other devices.

As an alternative, if you have a keyboard controller and one other MIDI device, you can run one cable from the OUT port on the controller to the IN port on the Apple MIDI interface, and then run the other MIDI cable from the OUT port on the Apple MIDI interface to the IN port of the second MIDI device.

There is no reason to connect a cable from the Apple MIDI interface to the IN port of the controller -- a controller does not play music.

MultiFinder: Workaround for Incompatible Desk Accessories

=====

Article Created: 21 January 1988
Article Last Reviewed: 15 October 1991
Article Last Updated: 15 October 1991

TOPIC -----

Why do some desk accessories work with MultiFinder and others do not?

DISCUSSION -----

Some desk accessories do not work properly under the MultiFinder DA Handler (version 1.0). If you open the DA while holding down the Option key, the DA loads into the present application's heap. This will allow some (but not all) MultiFinder-incompatible DAs to work correctly.

If you have a DA that is used in one application only, you may install it into that application using the Font/DA mover. This allows you to open the DA in the application's heap without having to hold down the Option key.

TOPIC -----

What are the pinouts for the Macintosh SE Bus Drive Card and PC 5.25" Drive?

DISCUSSION -----

Here are the pinouts for the internal cable, part number 590-0600, for the SE Bus Drive Card. It has a 26-pin in-line connector on one end for the card itself and a DB-37 connector on the other for the PC 5.25" Drive.

26 pin connector		DB-37 connector	

Signal Name			
1	----- GND -----		2
2	----- Side 1 -----		18
3	----- GND -----		NC
4	----- Read Data -----		17
5	----- GND -----		5
6	----- Write Protect -----		16
7	----- GND -----		NC
8	----- Track 00 -----		15
9	----- GND -----		NC
10	----- Write Enable -----		14
11	----- GND -----		NC
12	----- Write Data -----		13
13	----- GND -----		NC
14	----- STEP -----		12
15	----- GND -----		NC
16	----- Direction -----		11
17	----- GND -----		NC
18	----- Drive Select 0 -----		9

19	-----	GND	-----	20
20	-----	Motor Drive 0	-----	7
21	-----	Diskette Change	-----	19
22	-----	INDEX	-----	6
23	-----	+12 Volts	-----	1
24	-----	+ 5 Volts	-----	NC
25	-----	+12 Volts	-----	NC
26	-----	+ 5 Volts	-----	4

Here is the pinout for the DB37 connector on the Macintosh SE-Bus Drive Card
Note that pins not listed are not used.

DB37	Signal Name
1	----- +12 Volts
2	----- Ground
4	----- + 5 Volts
5	----- Ground
6	----- INDEX
7	----- Motor Enable
8	----- Drive Select 1
9	----- Motor enable
11	----- Direction
12	----- STEP

Macintosh Applications under A/UX (9/94)

Revised: 9/9/94
Security: Everyone

Macintosh Applications under A/UX (9/94)

=====
Article Created: 31 March 1988
Article Last Reviewed: 9 September 1994

TOPIC -----

In general, Macintosh applications that are "absolutely well behaved" (that follow the guidelines in Inside Macintosh) can be launched under A/UX.

DISCUSSION -----

Many of the non-compatible programs have programming flaws dealing with null pointers and handles. Because the Macintosh OS uses only 24 of the 32 bit address lines, many programmers have taken short cuts to handle locking by using one of the eight non-utilized bits as a locking status bit. But A/UX recognizes all 32 bits, and programs using those upper eight bits as status have major problems.

A/UX 2.0, 2.0.1, and 3.0 have a 24-bit compatability mode (it is a login session type) that will allow customers to run older, poorly behaved applications.

A/UX: The INET Daemon and Network Services (8/94)

Article Created: 31 March 1988
Article Reviewed/Updated: 23 August 1994

TOPIC -----

This article expands on the information in `inetd(1M)`, `servers(4)`, `services(4)`, the "inittab" file, and in the Network System Administration Manual.

DISCUSSION -----

"inetd" is one of the networking daemons (Internet super-server as quoted by the man page) started up ("fork"ed and "exec"ed) when the "init" process reads the "inittab" file and "net9"'s action field is "respawn". The inetd program waits for some process to connect to one of the "servers" that the inet daemon supports (found in `/etc/servers`). Only when the connection request comes in does inetd fire up ("fork" and "exec") the associated server process. It then continues listening for other connection requests (distinguished by the unique combination of the protocol type, Internet address, and port number).

In other words, "inetd" doesn't fire up all the "servers" listed in the `/etc/servers` file just because the "service" is listed in the file. There must be a connection request for that service before it is invoked. At this point, let's clear up possible confusion between `/etc/servers` and `/etc/services`.

The servers file contains the servers ("services") that our A/UX Internet daemon supports. Additionally, "inetd" calls "getservent," which reads `/etc/services` for more information such as port number, etc. This file references all the known services on the DARPA Internet. A simple analogy: `/etc/services` is the dictionary and `/etc/servers` are the words in your vocabulary.

You could theoretically run "inetd" in background mode and it would act the same as being spawned from the "inittab" file -- EXCEPT for one crucial thing. If the daemon quits for some reason, it would not be automatically reinvoked ("respawned") as it does when it is read from the inittab file with the "respawn" action (see `inittab(4)` for more information on "respawn").

Why are some network services handled by init reading "/etc/inittab" and others invoked by "inetd"? The network services listed in "/etc/inittab" are:

- portmap
- ypserv
- ypbind
- nfsd
- biod
- in.routed
- in.rwhod
- named

Each of these programs must be running all the time in a network environment for reasons like caching, performance, and availability for completion of a network requests. These "services" can't be called to life when a connection request comes in and then dropped when the connection request has completed, because these programs maintain the network and must be around at all times. Therefore, we must fire them up during the creation of the networking environment.

Services that do a task, then quit, are the services listed in the /etc/servers file.

Macintosh: Macros Files

=====

Article Created: 2 Februry 1988

Article Change History

08/31/92 - REVIEWED
• For technical accuracy.

TOPIC -----

Macintosh macros files.

DISCUSSION -----

It is possible for Macintosh users to create macro files to automate repetitive system functions (similar to .BAT and .COM files in MS-DOS).

In the Macintosh OS, this is possible within the MPW Shell and with Manx C.

On a Macintosh II with A/UX, this can be done with shell scripts within the C, Bourne, and Korn programming environments.

For more information, see the documentation that accompanies these products.

The Finder doesn't allow these capabilities from the Desktop.

How To Boot A/UX From "startup#" Prompt or on Startup (8/94)

=====

Article Created: 2 February 1988
Article Reviewed/Updated: 23 August 1994

TOPIC -----

How do you boot A/UX from the startup shell? How do you cause A/UX to boot automatically on machine startup?

DISCUSSION -----

Initially, to enter A/UX Startup you must cancel the startup process for A/UX. Once in the A/UX Startup shell, you see a command line prompt. The default prompt is "startup#".

To boot the system from here, pull down the "Execute" menu and select "Boot". This will launch the A/UX boot program. You can also type "launch" on the command line and press Return.

To have the Macintosh operating system automatically boot A/UX on machine startup, pull down the "Preferences" menu and select "Booting...". Place an "X" in front of the option that says "Automatically Boot at startup". Then click "OK".

Refer to the A/UX Local System Administration manual chapter on System Startup and Shutdown for more information.

Article Change History:
23 Aug 1994 - Updated to describe the startup shell.

A/UX: Multi-User Accessibility (8/94)

=====

Article Created: 2 February 1988
Article Reviewed/Updated: 23 August 1994

TOPIC -----

Can A/UX be used as a multi-user system?

DISCUSSION -----

A/UX is primarily a multi-tasking system. It can be operated as a multi-user system, but A/UX is NOT expressly designed to be a central system for multiple users -- at least, not as most people would view a true multi-user system.

The idea behind A/UX on the Macintosh is to have multiple stations, networked together, that can share resources.

Multiple users can interface with the Macintosh through Ethernet, or through the serial communication ports.

A/UX Display Driver Is Modeled After UNIX Form

=====

Article Created: 2 February 1988

Article Change History

08/31/92 - REVIEWED
• For technical accuracy.

TOPIC -----

Some Apple UNIX (A/UX) users have asked whether the display drivers used under A/UX are pure UNIX form drivers, or dependent on the display routines in the Macintosh Toolbox.

DISCUSSION -----

The display driver in A/UX is a text-based driver modeled after "STREAMS", a UNIX form driver. A/UX's display driver is a full implementation of a UNIX form driver, minus the multiplexing functions. The shell and UNIX-executable files that are part of A/UX are text-based.

Most of the Macintosh ToolBox routines are accessible through A/UX as library calls. These routines may be used in applications to create Macintosh environments, just as with Macintosh OS applications.

HyperCard: How to Open a Stack That Closes Itself

=====

This article last reviewed: 22 January 1988

If you find that you've accidentally created a HyperCard stack that closes itself immediately upon opening -- and you can't edit it to correct the problem, here's a way to force it to stay open.

In your home stack, make a button with this script:

```
on mouseUp
    set lockmessages to true
    go to stack "xyz"
end mouseUp
```

where "xyz" is the name of the problem stack. This will open the stack and leave you at the first card.

EtherTalk Node Limits

=====

This article last reviewed: 1 February 1988

Here are the answers to several questions regarding the EtherTalk card and the associated control panel cdev for choosing a network connection.

- When you switch from local AppleTalk to the EtherTalk card, the node number is renegotiated using the Apple Address Resolution Protocol (ARP). The AppleTalk session is restarted -- you don't have to reboot the system.
- If all 254 nodes are in use, the system will be physically attached to the network but will be logically unattached. No errors will be reported. The Ethertalk can still be used for other protocol suites such as TCP/IP -- the 254-node limit applies only to EtherTalk Cards and bridges running the AppleTalk protocol.

Backup II: Use ProDOS 1.2, Not ProDOS 1.4

=====

This article last reviewed: 22 January 1988

There were numerous changes made from ProDOS 1.1.1 to 1.4, perhaps too many for Backup II. Backup II was never updated to take advantage of the latest version of ProDOS, which supports the Apple IIGS.

If you're using Backup II, we suggest you go back to ProDOS 1.2 instead of 1.4, to have fewer changes in the operating system. By not using ProDOS 1.4, all you'll be giving up is support for the Apple IIGS. ProDOS versions 1.3 and 1.2 work correctly on other systems, just not on the Apple IIGS.

AppleShare: It Cannot Limit Access By Location

=====

This article last reviewed: 9 February 1988

The AppleShare server is designed to limit access by individual, not by geographical location. So it's not possible, for example, for an individual user to have differing access privileges depending on which workstation he's using at the moment.

Once networks are connected, it's not possible through AppleShare or the Chooser to limit inter-network access. Unless you're using a mail system or other system communication that requires inter-network access, it may be best not to connect your networks.

System 4.2 / Finder 6.0: It Can Corrupt Fond Resources

=====

Article Created: 13 February 1991
Article Last Reviewed: 6 November 1991
Article Last Updated: 6 November 1991

TOPIC -----

This article describes font problems that may occur with System 4.2, Finder 6.0, and LaserWriter 5.0.

DISCUSSION -----

There is a problem in the new system software (System 4.2, Finder 6.0, and LaserWriter 5.0) that sometimes corrupts the Fond resource. This can cause inconsistent results when documents are created under older system software then opened or printed under the new system software.

To correct the offending Fond resource, use Font D/A Mover 3.6 to remove the offending fonts (all sizes), and reinstall them. This forces the font table to be recreated.

Another solution would be to update to a current version of System Software.

MacWorkStation: It Can Support User-written Code

=====

This article last reviewed: 9 February 1988

A host program can send a message to MacWorkStation telling it to execute a code module. The code modules should be in a resource whose ID is passed in the message. It is also possible to pass data or parameters to the code module.

MacDraw: It Doesn't Have a True Tab Function

=====

This article last reviewed: 9 February 1988

MacDraw does not support a true tab function.

When the tab key is pressed in MacDraw, a representation of the character is displayed. For example, the Courier tab character has a width, whereas the Helvetica tab character does not -- so Courier moves the insertion point over the width of the tab character.

This is not really the tab function that is written into many other applications, which inserts a defined amount of space when a tab (ASCII code 9, horizontal tab) is received. With a tab function, it's not the character width being displayed, but the code being interpreted by the application, which inserts the defined amount of space.

There is no correlation between a space or tabs in MacDraw. The tab differs, different depending on the font selected and whether the tab character has been given a character width.

IBM 9375 and Macintosh 327x Connectivity

Revised: 10/4/89
Security: Everyone

IBM 9375 and Macintosh 327x Connectivity

=====

This article last reviewed: 10 February 1988

Because the IBM 9375 is a member of the 370 family, 3725s can be attached and AppleLine, Avatar, and MacIrma can be connected. The NetWay requires a specific ICA (Integrated Communications Adapter), one with a Sync RS-232 port, to function with this system.

The 937X processor contains a communications processor card, which can be thought of as the hardware equivalent of a 3725. This processor card can support a number of line adapter cards that interface with devices such as 3174 and 3274s. The ICA is therefore functionally equivalent to a 3725, a 3174, or a 3274.

Printing Postscript to DEC's LN03R Printer

Revised: 2/13/88
Security: Everyone

Printing Postscript to DEC's LN03R Printer

=====

This article last reviewed: 10 February 1988

When printing Postscript output from LaserWriter drivers to a DEC LN03R printer (LaserWriter Plus compatible) attached to a VAX, you may encounter an INVALID ACCESS ATTEMPT error for the SETDEFAULT TIMEOUTS command. When this command is removed, another error of UNDEFINED: NAME NOT FOUND is reported for the LEGAL command.

According to Adobe, you need to exit the server loop to use the setdefaulttimeout operator. The code is:

```
statusdict begin 0 exitserver
```

DEC's LN03 is LaserWriter-compatible from the Postscript side of things, but there are differences with respect to hardware options.

Zapf Chancery Font: Why It Doesn't Print Bold or Italic

=====

This article last reviewed: 9 February 1988

Although you can produce italic and bold characters on the screen with the Zapf Chancery font, when you print them they'll seem to be plain.

Actually, plain Zapf Chancery is italic to start with and it has no bold style. Observe the delicate and precise curves of the normal style of Zapf Chancery: making it bold would fill in most of the open areas on the smaller sizes.

ImageWriter: Printing from MS-DOS (9/94)

=====

Article Created: 13 February 1988
Article Reviewed/Updated: 30 September 1994

TOPIC -----

Does Apple have any driver that supports printing to a ImageWriter, ImageWriter II, or an ImageWriter LQ from a MS-DOS compatible?

DISCUSSION -----

There is no driver that supports printing to any of the ImageWriter family of printers from MS-DOS or Windows that is made by Apple Computer, Inc. Microsoft Windows has a driver named "C-Itoh 8510" that may work with the ImageWriter II (with no LocalTalk option card) if the proper cable is used.

With the appropriate driver, it is possible for an MS-DOS computer with the AppleTalk PC Card to print to an ImageWriter II or AppleTalk ImageWriter LQ over LocalTalk. However, Apple Technical Communications is not, at this writing, aware of such a driver.

Macintosh II: It Requires 120ns RAM Chips Or Faster

Revised: 7/21/92
Security: Everyone

Macintosh II: It Requires 120ns RAM Chips Or Faster

=====

Article Created: 6 November 1988
Article Last Reviewed: 21 July 1992
Article Last Updated:

TOPIC -----

I know the Macintosh II requires SIMMs that are 120ns or faster. What problems will I run into with using ones that are slower?

DISCUSSION -----

Apple recommends and supports only 120ns or faster RAM chips for the Macintosh II.

In theory, the Macintosh II does not operate properly with SIMMs containing RAM chips slower than 120ns. This is because the number of RAM wait states defined in ROM does not change dynamically to accommodate slower RAM. (This is not an issue with the Macintosh Plus and Macintosh SE because their slower processor clock speed accomodates slower RAM speeds.)

In practice, however, slower RAM chips (150ns, for example) will work on a Macintosh II because RAM chips are often faster than their labelled ratings. Nevertheless, always use RAM that is tested and rated at the required speed of the computer. Otherwise, you may eventually experience random system crashes or other inconsistent errors using SIMMs slower than 120ns.

(NOTE: Macintosh Plus and Macintosh SE do NOT dynamically allocate wait states according to memory speed.)

TOPIC -----

Can I use my Macintosh II in a vertical orientation?

DISCUSSION -----

A Macintosh II, or Macintosh IIX and Macintosh IIIfx, should always be kept horizontal.

Standing it on end

- voids the warranty
- defeats the cooling design
- will eventually damage the main unit.

The above remains true even if the required 4 to 6 inches of clearance is maintained around the vents.

ImageWriter LQ: Spacing Problem In "Best" Mode Caused By Driver

=====

Article Created: 13 February 1988
Article Last Reviewed: 6 November 1991
Article Last Updated: 6 November 1991

TOPIC -----

This article describes spacing problems with the earlier version of the ImageWriter LQ print driver, version 1.x.

DISCUSSION -----

In the box with the ImageWriter LQ is a sheet titled "ImageWriter LQ Important Information." It says: "Macintosh users: Words printed in Best Mode may occasionally touch or overlap, depending on the font, font size, or font style you use. To correct any spacing problems, try adding one or more spaces between words that are too close together."

The problem is not with the ImageWriter LQ itself, but with the ImageWriter LQ driver.

The solution is to upgrade to the ImageWriter LQ 2.0 driver.

Applesoft BASIC: Advancing to Next Line After a ProDOS Call

=====

This article last reviewed: 5 February 1988

When you add a function to ProDOS and call the function from BASIC, you don't then return to the BASIC program that called the routine: at that point, you are BASIC. If the added function is more than one word (as specified in the ProDOS Technical Reference Manual), the pointer that should automatically take you to the start of the next line is not updated properly.

You must make a call to Applesoft to go to the end of the current line, which automatically sets the pointer to the start of the next line.

There is a specific call in Applesoft to make this happen. In the Tech Info Library, search on:

AppleTalk ImageWriter: Avoiding Timeout Problems

=====

This article last reviewed: 5 February 1988

How an application, or driver, is written is what determines whether it works correctly in all instances with networked printers. If a program or driver is 'disconnected' from the printer long enough for the AppleTalk option card to timeout, the rest of the print job may be lost.

Two ways to avoid having this happen:

- When using manual feed, don't wait for a page to finish before responding to screen prompts -- this will help you avoid AppleTalk option card timeouts.
- Use a cut-sheet feeder, which lets you use the paper you want without having to use manual feed with its attendant pauses.

ProDOS Can't Handle Disk Volumes Larger Than 32MB

=====

This article last reviewed: 5 February 1988

Current versions of ProDOS can't handle more than 32MB of storage on a hard disk volume.

If you connect a Hard Disk 40SC or Hard Disk 80SC to an Apple II, you must partition the hard disk -- that is, divide it into separate volumes. Each volume is then counted as one SCSI device.

Apple does not supply the software that does the partitioning and currently does not know of any other source for such software.

A/UX: List of Included Berkeley Utilities (8/94)

Article Created: 5 February 1988
Article Reviewed/Updated: 23 August 1994

TOPIC -----

A/UX: List of Included Berkeley Utilities. This list was originally compiled for A/UX 1.0 but is still applicable to later versions.

DISCUSSION -----

Berkeley Enhancements

Although A/UX is primarily based on AT&T System V, Apple has added many of the more popular and useful utilities from BSD 4.X (U.C. Berkeley's version of UNIX).

A/UX supports the following 4.2 BSD utilities:

addbib:create or extend bibliographic database
adventure:an exploration game
aliens:alien invaders attack the earth
apply:apply a command to a set of arguments
apropos:locate commands by keyword lookup
banner7:print large banner on printer
bcd:convert to antique media
biff:be notified if mail arrives and who it is from
ccat:compress and uncompress files, and cat them
chase:escape the killer robots
checknr:check nroff/troff files
chfn:change full name of user
chsh:change default login shell
clear:clears the user's terminal screen
colcrt:filter nroff output for CRT previewing
colrm:remove columns from a file
compact:compress and uncompress files, and cat them
cribbage:the card game cribbage

ctags:maintain a tags file for a C program
ctags:processes a source program to allow ex/vi editors to quickly find
function and type definitions.
diction:print wordy sentences; thesaurus for diction
dump:incremental file system dump
expand:expand tabs to spaces, and vice versa
eyacc:modified yacc allowing much improved error recovery
finger:user information lookup program
fish:"go fish" card game
fmt:simple text formatter
fold:fold long lines for finite width output device
fortune:print a random, hopefully interesting, adage
fpr:print Fortran file
from:who is my mail from?
fsplit:split f77, ratfor, or efl files
ftp:file transfer program
groups:show group memberships
head:print the first few lines of a file
hostname:set or print name of current host system
indent:indent and format C program source
indxbib:build inverted index for a bibliography, find references in a
bibliography
last:indicate last logins of a user
leave:remind you when you have to leave
lookbib:find and insert literature references in documents
lpc:line printer control program
lpd:line printer daemon
lpq:spool queue examination program
lpr:line printer spooler
lprm:remove jobs from the line printer spooling queue
ls7:list contents of directories BSD style
mkstr:create an error message file by massaging C source
netstat:show network status
number:convert Arabic numerals to English
pagesize:print system page size
printenv:print out the environment
rain:animated raindrops display
rcp:remote file copy
rdump:file system dump across the network
refer:find and insert literature references in documents
remsh:remote shell
renice:alter priority of running process by changing nice
reset:reset the terminal to a known state
restore:incremental file system restore
rev:reverse lines of a file
rlogin:remote login
roffbib:run off bibliographic database
rrestore:restore a file system dump across the network
ruptime:show host status of local machines on a network
rwho:who's logged in on local machines
sccs:front end to SCCS
script:make typescript of terminal session
see:see what a file has in it

soelim:eliminate .so's from nroff input
sortbib:sort bibliographic database
strings:find the printable strings in a object, or other binary file
style:analyze surface characteristics of a document
sysline:display system status on status line of a terminal
talk:talk to another user
telnet:user interface to the TELNET protocol
tip:connect to a remote system
trek:trekkie game
tset:set terminal modes to its power-on settings
ul:interprets backspacing to format underlining for line printers
uncompact:compress and uncompress files, and cat them
unexpand:expand tabs to spaces, and vice versa
uptime:show how long system has been up
users:compact list of users who are on the system
uudecode:encode/decode a binary file for transmission via mail
uuencode:encode/decode a binary file for transmission via mail
uusend:send a file to a remote host
vipw:edit the passwd file with vi
w:who is on and what they are doing
whatis:describe what a command is
whereis:locate source, binary, and or manual for program
which:locate a program file including aliases and paths (under csh only)
whoami:print effective current user id
worm:the growing worm game
worms:animate worms on a display terminal
xstr:extract strings from C programs to implement shared strings
yes:be repetively affirmative

C Shell

Also included is the U.C. Berkeley command interpreter (C shell). The C shell (csh) is a command interpreter that originated at the University of California at Berkeley. Its command language is somewhat like the C programming language. In addition to the C-like control flow features of its command language, the C shell also has a command history mechanism that enables the user to repeat and edit previous commands, permits commands to have an alternative name or alias, and has built-in job control functions.

Descriptions of the following commands and built-in functions can be found in the "csh(1)" man pages.

alias
break
breaksw
case
cd
chdir
continue
default

Macintosh Computers: ROM Version Numbers (2/97)

=====

Article Created: 26 June 1990
Article Reviewed/Updated: 24 February 1997

TOPIC -----

How do I determine the ROM version of my Macintosh computer?

DISCUSSION -----

Use the Programmer's Interrupt Switch to determine the ROM version number of your Macintosh Computer.

Step 1

Press the (programmer's) interrupt switch, or use the keyboard equivalent.

Step 2

Type:

DM 2AE

Step 3

Press return.

This displays the ROMbase global which is located at memory address \$0002AE. The ROMbase global is the number located in offset 0 and 2.

For example, a Quadra 660AV displays:
4080 0000 XXXX XXXX XXXX XXXX XXXX XXXX

Step 4

Type the ROMbase global

EXAMPLE: DM 40800000

The result is 5BF1 0FD1 0000 002A 077D XXXX XXXX XXXX

Step 5

The machine type and ROM version are at offset 8 or 077D in this case which is from a 660av Macintosh Computer. You could also add the 8 bytes to the memory address and have done DM 40800008 and the first two bytes would be the type and ID.

Macintosh ROM Version Table

System	Machine Type	ROM version
-----	-----	-----
Macintosh 128K	00	
Macintosh 512K	00	
Macintosh 512Ke	00	75

LaserWriter IIntx: Don't Try To Put Macintosh II SIMMs In It

=====

This article last reviewed: 10 February 1988

There is no way to plug a Macintosh II SIMM into a LaserWriter IINTX, or vice versa. The two SIMMs are incompatible both physically and electrically.

The LaserWriter IINTX SIMM is .25" longer than a Macintosh II SIMM.

The LaserWriter IINTX SIMM has 128 contacts on the module, in four groups of 32 (64 on each side).

The Macintosh II SIMM has 60 contacts, 30 on each side of the module.

What's the difference between tick rates and draw rates?

DISCUSSION -----

On all Macintosh computers, the tick rate is 60 ticks per second, regardless of processor type or speed. Ticks are available to the programmer to provide timing sequences that are constant, independent of machine type or the application.

Two different applications, on the other hand, may draw objects on the screen at varying rates, but this is due to the different drawing algorithms the applications use -- not to varying tick rates.

And the same application may draw at different speeds on different machines. For example, certain QuickDraw routines perform about 20 percent faster on a Macintosh SE than they do on a Macintosh Plus, due to the way memory is accessed. The Macintosh II, depending on video card settings, performs QuickDraw routines two to four times faster than a Macintosh Plus, because of its 68020 processor.

Some other factors that affect how fast a Macintosh draws an object on the screen:

- INITs
- VBL tasks
- hardware interrupts
- software interrupts
- Time Manager calls
- QuickDraw overhead
- memory

Apple Video Card and Monitor: Gray Scale Specifications

Revised: 7/2/92
Security: Everyone

Apple Video Card and Monitor: "Gray Scale" Specifications

=====

Article Created: 22 January 1988
Article Last Reviewed: 30 June 1992
Article Last Updated:

TOPIC -----

The gray-scale capabilities of Apple video monitors are no different from those of other gray-scale monitors. ("Gray scale" is another name for a monochrome analog monitor.)

DISCUSSION -----

The Apple Macintosh II Video Card produces true gray-scale output, in the form of an analog RS-343 standard video signal. Apple monitors are also capable of displaying true gray-scale images. The RGB monitor even displays color information.

Apple's video displays 256 shades of gray (or colors) on an analog monitor. Some manufacturers have video cards that display up to 786,432 shades of gray or colors. Apple video cards have access to the same source (16.8 million different shades of gray or colors) as these others--the differences in the number of gray and color shades is due only to the amount of memory on the video card.

Security: Everyone

HyperCard: Two Methods For Speeding Up New Sound Retrieval

=====

This article last reviewed: 27 January 1988

If you want to load new sound resources into memory so that they can be accessed quickly on HyperCard -- normal drive response takes several seconds, which may be too long a delay for certain projects -- try one of these two methods:

- store the sounds on a small RAM disk

or

- use a resource editor such as ResEdit to PRELOAD the sound resources that you wish to speed up.

There are limitations to this preloading method: the initial stack launch time is slowed, and some sounds may be too large to reside in memory.

(NOTE: Make sure you back up your original stack before attempting this.)

Security: Everyone

Apple Hardware: International Certification Information

=====

Article Created: 2 September 1988
Article Last Reviewed: 23 June 1992
Article Last Updated: 23 April 1991

TOPIC -----

What types of international certification does Apple equipment meet?

DISCUSSION -----

Depending on the particular piece of equipment and the country in which it is distributed, all Apple equipment meets the following codes and standards:

- UL 544/478
- CSA
- VDE 0871
- FCC class B certification

Some Macintosh hardware, and other Apple Equipment, is produced in more than one version to meet specific country requirements. For example, Macintosh II monitors are built specifically for Germany to meet the VDE 0871 certification. Domestic Macintosh II monitors do NOT carry the VDE certification label.

Apple equipment is also tested by the following European countries and/or organizations prior to distribution.

SIMKO/Sweden
DEMKO/Denmark
NEMKO/Norway
FEI/Finland
Bureau of Viritas/Spain
AIB-Vincotte/Belgium

NOTE: Currently, Apple Computer does not test Apple equipment for hospital AAMI/ANSI compliance certifications. However, depending on an individual institution's certification requirements, Apple equipment may possibly be used in certain work areas. Before installing equipment, Apple customers need to check the hospitals certification requirements for the work area where the equipment is to be installed.

Apple equipment distributed in Belgium must meet the NBN C 79-204/NBN C 77-380 standards.

Almost all Apple Equipment is labelled with its exact certifications.

Macintosh Built in Serial Ports: Not Identical

=====

Article Created: 25 January 1988
Article Last Reviewed: 9 June 1992
Article Last Updated:

TOPIC -----

Are there any differences between the two built-in serial ports on Macintosh computers?

DISCUSSION -----

The two built-in serial ports on Macintosh products are nearly identical, except for the differences detailed in this article. Here are the differences:

- Port A (the modem port) has a higher interrupt priority; it is more suitable for high-speed transmission.

Ordinarily, Port B (the printer port) should be used for output-only connections, or at low baud rates; the Port A (the modem port) has no such restrictions. Whenever interrupts are turned off for longer than 100 microseconds, the Serial Driver stores any data received through Port A (the modem port,) and later passes the data to the modem port's input driver.

Note: For more information, see "Inside Macintosh Volume 2."

- Port A on the Macintosh SE and Port A on the Macintosh II support synchronous transmission, but Port B does not. Earlier Macintosh products do not support synchronous transmission through either port.

MultiFinder: Works With TOPS 2.0 and Single Drive

=====

Article Created: 21 January 1988
Article Last Reviewed: 16 October 1991
Article Last Updated: 16 October 1991

TOPIC -----

Will MultiFinder work with TOPS (version 2.0)?

DISCUSSION -----

MultiFinder works with TOPS version 2.0, and disk space can be found to use it with only a single floppy drive.

A bootable Macintosh disk using System Software 5.0 with MultiFinder requires at least these files:

- System
- Finder
- MultiFinder

You can save more room by removing unneeded desk accessories and Fonts from the System file. The System file must contain the TOPS DA, and four fonts: Chicago 12, Monaco 9, Geneva 9, and Geneva 12. All other fonts and DAs can be removed to save space.

NOTE: If you plan to access the Control Panel, you will need that DA installed, along with the CDEVs necessary to perform the desired functions: "General", for example.

We suggest you pare down a System 5.0 disk to your minimum requirements, leaving as much disk space as possible, then install TOPS 2.0.

"No AppleTalk ImageWriter LQ" Message May Be Bad Software/Card

=====

This article last reviewed: 26 January 1988

Have you had this problem while using AppleTalk and an ImageWriter LQ?:

- Upon starting the application "The Namer" and selecting the AppleTalk ImageWriter LQ icon, you get a message saying that NO AppleTalk ImageWriter LQ is connected to the network -- even though one is properly connected?

Rather than a configuration problem, you are probably using corrupted software or a bad AppleTalk card. Try the job again with one or both of these variables replaced.

ALERT: Beware of "Sexy Ladies" Program

=====

Article Created: 3 February 1988
Article Last Reviewed: 20 May 1992
Article Last Updated:

*** IMPORTANT ***

Watch out for a Trojan Horse program that was distributed at MacWorld in January 1988. It's called "Sexy Ladies". When you run the program, it puts an abusive message on your screen, then ERASES your hard drive. It was distributed on a floppy named "PD".

To prevent viruses and Trojan Horses from affecting your system, make sure you:

- Know the source of an application before using it.
- Try out any dubious programs on a test system.

For more information, please search on the term VIRUS.

Macintosh Finder: How View Affects File Opening Order

=====

Article Created: 3 February 1988
Article Last Reviewed: 2 February 1991
Article Last Updated:

TOPIC -----

Why is it that when I surround multiple files in the Macintosh Finder 6.X with a selection rectangle, and then choose Open from the File menu, the order in which files open varies?

DISCUSSION -----

When you use the selection rectangle (also called a "marquee" or "marching ants"), the "View" you have selected affects the order in which the files open. Here are the view selections and their results:

- By Icon or By Small Icon: The most recently added, moved, clicked on, or changed file opens last. The next most recently added, moved, clicked on, or changed file opens NEXT to last, and so on.
- By Name: The files open in descending alphabetical order; for example, "Zero" would open after "Alice".
- By Date: The files open in last-modified date order; that is, the most recently modified file opens last.
- By Size: The files open in size order, smallest file opening last.
- By Kind: The files open in alphabetical order based on the kind of file. For example, a document file opens after an application file.
- By Color: The files open according to the color of their icons, based on the order of colors in the Finder's Color menu. The last color in the list opens last.

Macintosh SE: Companies That Supply Option Card Products (8/94)

Article Created: 1 February 1988
Article Reviewed/Updated: 8 August 1994

TOPIC -----

The following companies produce option cards for the Macintosh SE expansion slot.

DISCUSSION -----

Expansion Chassis

ExpanSE -- from Second Wave, Inc. -- is an expansion chassis for the Macintosh SE. Its interface occupies the SE expansion slot, providing four slots. For more information on ExpanSE, search under: Second Wave, Inc.

Option Cards

The following companies have announced SE option card products for the Macintosh SE.

Please pay particular attention to the ADDRESS RANGES used by these SE option card products. To select a combination of four products to use in a Second Wave ExpanSE expansion chassis, choose products without overlapping address ranges. Products with switch-selectable addressing are the most flexible products to use in your chassis.

(NOTE: Information was not available for all products.)

Mac86: >800000->8FFFFFF
- AST Research, Inc.

MacMainFrame SE: >800000->81FFFF
- Avatar Technologies, Inc.

MacIRMA: Switch-selectable addressing

- Digital Communications Associates (DCA)

Epic 2400SE: Switch-selectable addressing

- Epic Technology, Inc.

The Big Picture: >780000->799400

- E-Machines Inc.

HyperCharger 020

- General Computer Corporation

(NOTE: does not implement the Apple 68000 bus protocol completely, and will therefore not operate in ExpanSE)

Pro Board by Addon Computer Corp.

- IO Inc.

EtherPort SE: >800000->80FFFF

- Kinetics, Inc.

Turbo SE: Math co-processor: >500000->50FFFF

>C00000->C7FFFF, >F80000->F9FFFF

- Radius, Inc.

Inspector

- Seawell Microsystems

LaserView: >800000->8FFFFFF, >C00000->CFFFFFF

- Sigma Designs, Inc.

Analog Connection SE-12

Analog Connection SE-16

- Strawberry Tree Computers, Inc.

SuperView: Rev. C uses>A00000->AFFFFFF, Rev. E uses >C00000->C4008D &
>F80000->FBFFFF, the 68881 uses >C80000->C9FFFF

- SuperMac Technology

Apple PC 5.25 Drive: >800000->8FFFFFF

- Apple Computer, Inc.

NOTE

The Apple card does not strictly adhere to the 68000 Bus Arbitration Protocol. This protocol requires that after a bus request has been made and granted, the requesting device should send back a 'bus grant acknowledge' -- something the Apple card does not do.

In the case of Second Wave's ExpanSE, this signal notifies the processor to turn the trancivers around and guarantee full communication. Without this signal, the trancivers are never turned and an error message is returned -- "Unable to Read Disk" -- as the communication is only in one direction.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Apple IIGS Workstation Software: New Product Information

Revised: 5/25/89
Security: Everyone

Apple IIGS Workstation Software: New Product Information

=====

This article last reviewed: 1 March 1988

Overview

Apple IIGS Workstation Software lets you connect an Apple IIGS to a LocalTalk network. This software performs the same function as the Apple II Workstation Card for the Apple IIe. The software makes it possible to start up from an AppleShare File Server 2.0 and run an Apple IIGS without disk drives attached.

The only additional hardware needed is an Apple IIGS Memory Expansion Card containing at least 512K of RAM, and a LocalTalk System Connector Kit.

Apple IIGS Setup

Before you can use the Apple IIGS on the AppleTalk Network System, you must configure the system correctly.

From the Control Panel (accessed via Open Apple-Control-Esc):

1. Be sure the Maximum RAM Disk Size is at least 256K less than the Largest Selectable. For example, if the Largest Selectable is 1024K, then set the Maximum RAM Disk Size to 768K or less. The default value of 0K is best if you plan to run any Apple IIGS specific programs.

Control Panel	
RAM Disk	
X Minimum RAM Disk Size:	0K
X Maximum RAM Disk Size:	0K
-Largest Selectable	1024K-
-RAM Status-	

RAM Disk Size:	0K
Total Ram in Use:	84K
Total Free RAM:	1195K

(The numbers following Total RAM in Use and Total Free RAM will vary, depending on phase of startup process.)

2. Set Slot 1 or Slot 2 to "Your Card" (Slot 1 is recommended).

- If slot 1 = "Your Card", plug LocalTalk connector into the Printer Port.
- If slot 2 = "Your Card", plug LocalTalk connector into the Modem Port.

3. Set Slot 7 to "Built In AppleTalk"

4. Set Startup to Slot 7

Control Panel
Slots
Slot 1: Your Card
X Slot 2: Modem Port
X Slot 3: Built-in Text Display
X Slot 4: Mouse Port
X Slot 5: Smart Port
X Slot 6: Disk Port
Slot 7: Built-in AppleTalk
Startup Slot: 7

5. Exit the Control Panel. If you had to change the RAM Disk settings, you must POWER DOWN (with the power switch). This will reset the RAM Disk to the setting you have selected. It does not change RAM disk values until power down. This way, you can restart without loss of RAM Disk contents.

AppleShare File Server 2.0: New Product Information

Revised: 10/4/89
Security: Everyone

AppleShare File Server 2.0: New Product Information

=====

This article last reviewed: 1 March 1988

Overview

AppleShare File Server 2.0 (AFS) is an updated version of AppleShare. AFS allows you to store and share Macintosh documents, folders, and applications. The AFS software and your Macintosh Plus, Macintosh SE, or Macintosh II together create an AFS server. The server can run over any AppleTalk cable system, including LocalTalk and EtherTalk.

The rest of this article describes changes that have been made in AppleShare File Server 2.0.

Server Changes

AppleTalk Filing Protocol (AFP) 2.0

AFP has been modified to support Apple II workstations. AFP 2.0 is an extension of AFP 1.1. For more information, see "ProDOS Support" later in this article.

Large Volumes Start Up Faster

The time required to check each volume for consistency of the Parallel Directory Structure (PDS) has been reduced. During this process, all file and folders on the volume are cross-checked with the PDS file. The PDS file is used internally by AFS.

Automatic Repair At Startup

In the past, these errors were flagged, and you had to run the AppleShare Administrator to repair the PDS file. The server now repairs errors in the PDS when it finds a problem. This saves time, because you do not have to restart and run the AppleShare Administration program to start up your

server. If any repair is necessary, it will be listed in the AppleShare Messages listing.

Folder Locking

You can now lock a folder, thus preventing it from moving. The option is enabled from the Access Privileges desk accessory. Only the folder's owner can check or uncheck the folder lock option. When the folder is locked, ALL users are prevented from moving, renaming, and deleting the folder.

Support for Read-Only devices (CD-ROM)

AFS 2.0 supports HFS CDs. A PDS file and Desktop Database are created in the Server Folder on the startup volume. These files are created when the AppleShare Admin program is run to setup a CD volume. Only the Macintosh partition of the CD can be accessed by AFS. (AFS disables the option to eject the CD from the drive.)

From the workstation, you will see no difference (except volume size) in the server volumes. A CD is slower due, to the seek time of the drive. If multiple users are accessing different parts of the drive at the same time, there will be a noticeable slowdown.

Workstation

Set Password

Users can now change their passwords through the Chooser DA. An encrypted version of the password is sent to the Server, to ensure security for the password.

View Information

The view (by size, name, date, type...) of a file is set by the Owner of the folder. A user can change the view of a folder, but when the folder is opened by other AFS users, the view is set from the owner's settings.

Admin Changes

Online Administration

The AppleShare Administration program can be run concurrently with the AppleShare File Server 2.0. In the past, performing administrative tasks required bringing down AppleShare. AppleShare Admin now runs as a concurrent application -- so you can add users, groups, and perform other tasks while the AFS server is still running.

Administrator (Custodian)

AppleShare File Server 2.0 allows the Administrator to function as an all-knowing and all-powerful user. This is a special user that the old version of AppleShare called the custodian. The Administrator can see ALL

files and folders, create, rename, delete, and move files in any folder on the server volume, as if the administrator were the owner of the file or folder. The Administrator can also reassign any folder's owner, group, or access privileges.

Copy a volume

The Admin program lets you copy a full volume, keeping the access privileges intact for the entire volume. Although you can do this while the server is running, it's best to do it when the server is down. If you copy while the server is running, some files will not be copied, because of file locking. The server still allows users to access files, but in a very slow manner.

ProDOS Support

Apple II Admin Box

A check box to set up Apple II Administration is located in the Server Information box. Selecting this box creates the folder Users at the root level of the startup volume. It then creates a folder for each user, and places an empty Apple II boot file in each user folder. The administrator should have users entered in the User List before you perform this function.

After this box has been selected, a new APPLE II menu will appear, from which the administrator can set the printer, prefix, and startup application for each user. You first select the user from the user list, and then select Startup Information from the Apple II menu.

AppleShare Print Server: New Product Information

Revised: 11/2/88
Security: Everyone

AppleShare Print Server: New Product Information

=====

This article last reviewed: 1 March 1988

Overview

AppleShare Print Server (APS) is a new revision of the LaserShare print server.

- With APS, you can print a document without having to wait for an open printer.
- APS supports LocalTalk LaserWriters and LocalTalk ImageWriters.
- APS acts as a go-between for workstations and printers on your network.
- APS takes documents to be printed, temporarily stores them on disk, and sends them to the printer.
- The APS server is supported on a LocalTalk or EtherTalk network.
- APS can run either as a standalone application or as a concurrent application under AppleShare File Server 2.0. It does not run concurrently with older versions of AppleShare. You need to have a hard drive connected to the computer running APS.

The rest of this article describes the new features of the AppleShare Print Server.

Support of Multiple Printers

APS can act as a spooler for up to five printers. APS creates a new "printer" that is accessed from the chooser DA. Each printer that is spooled maintains a separate print log and print queue.

Warning: You can capture a printer in a different zone. The spooled printer

will appear, under Chooser, in the same zone as the APS server. If bypass printing, or allowing printing from both the spooler and workstation, is not allowed, the printer will no longer appear in the original zone. This can cause a user to think there is a problem with the printer. The user will have to select the zone of the APS server to see the spooled printer.

Automatic Reconnection To All Printers

When the APS server restarts, it connects with the printers and restarts any print jobs that were not completed.

Printer and Window Menu

To display the windows on the screen, select the printer and window from the Printer menu. This brings up a list of different printers, then uses a hierarchical menu to display the options, log, or queue window. (If the hierarchical menu does not come up, the user could be operating with older system software.)

You control the display of the queue, and log windows that appear on the screen, from the Window menu. There are options to Stack, Tile, or Hide the windows. You can also move the windows using standard Macintosh click and drag techniques. The server continues to spool documents, whether or not the queue or log windows are open.

Support of AppleTalk ImageWriter II and LQ

APS supports printing to the AppleTalk ImageWriter II and ImageWriter LQ. The Options dialog contains information about these printers.

When some applications print to an ImageWriter II or LQ, they treat each page as if it were a separate document. If two or more users print at the same time, pages from the various documents will be intermixed as they come off the printer. APS can group the pages into a single print job. This feature is called the Inter Page Timeout.

After APS receives a page from the workstation, it waits (five seconds is the default) to see if any more pages are sent from the same workstation. If APS receives another page in the allotted time, it assumes the page is part of the first document, and appends the page to the current document. If APS does not receive the document in the allotted time, APS assumes that it has received all of the document. If any additional pages come in, they are treated as a separate document.

Because applications differ in how long it takes to print a page, the time-out option is adjustable. You don't want to make the time between pages too large, because the spooler may combine two documents into one document. You can adjust the time-out from zero to 60 seconds, using Set intervals in the pop-up menu.

The LaserWriter logs list the Document Name and User Name. The ImageWriter drivers don't send the necessary information to display the Document and User Name, and the space is left blank. If you are printing a Draft style document to an ImageWriter printer, the first fifteen characters of the document appear in the document name field.

Print Queue and Logs

Print Queue and Print Log are now disk-based. The new maximum is 1,000 entries in each.

AppleCD SC: Using It With an Apple II

Revised: 5/17/89
Security: Everyone

AppleCD SC: Using It With an Apple II

=====

This article last reviewed: 29 February 1988

The AppleCD SC drive can be used with any Apple II that contains an Apple II SCSI Card with at least a revision C ROM. The recommended position is at the end of the SCSI chain. The drive must have a unique priority number on the SCSI bus. With the appropriate driver, you can access a compact disc that uses either audio, ProDOS, or High Sierra format.

The AppleCD SC's accessory kit contains a version of CD Remote software for both the Apple IIe and Apple IIGS.

- To play an audio CD from an Apple IIGS, copy the file CD.AUDIO from the Apple II disk (supplied with the AppleCD SC) to the DESK.ACCS folder on the Apple IIGS startup disk.
- On the Apple IIe, run the Apple IIe CD Remote program (included with the AppleCD SC drive).

A compact disc pressed in ProDOS format will be recognized by either ProDOS 8 or ProDOS 16, and used accordingly. ProDOS 8 retains its 32MB limitation, so compact discs are likely to be partitioned if they are intended to be used on an Apple IIe. ProDOS 16 is not limited to 32MB volume sizes.

Once a High Sierra driver is placed within the System Folder under ProDOS 16, the Apple IIGS will recognize a High Sierra disc as a storage device.

Because the Apple IIe doesn't support ProDOS 16, it can't take advantage of the Driver folder structure within the System Folder. Apple will supply interested developers with the High Sierra driver, which must then be incorporated into each application that supports High Sierra formatted discs on the Apple IIe.

The eject button on the AppleCD SC operates on all types of compact discs

used on an Apple II. As usual, if an application expects the volume to be on-line and the disc is ejected, ProDOS will ask the user to insert the disc.

AppleCD SC: General Description (Discontinued)

Revised: 6/1/94
Security: Everyone

AppleCD SC: General Description (Discontinued)

=====

This article last reviewed: 29 February 1988

The AppleCD SC is an audio-capable CD-ROM (Compact Disc - Read Only Media) device with Apple SCSI ports. This peripheral device, about the same size as an Apple SCSI hard disk drive, reads compact discs with up to 550 MB capacity.

Apple supports five formats for information on CDs:

- CD-Audio
- CD-ROM
- HFS
- ProDOS
- High Sierra

The AppleCD SC has a front-loading caddy for standard-size compact discs. The player accommodates stereo headphones or speakers through either the mini-phono jack in front or via the line level audio output ports in back of the device.

This compact disc player has second-generation CD hardware, which contains better error checking in firmware, a 64K RAM buffer, half-height size, better small-block handling capabilities, and better CD-Audio results than earlier CD-ROM players.

The AppleCD SC does a full-stroke seek and read in 500 milliseconds; its mode transfer rate is 154 KBytes per second. The hardware can recognize three compact disc data modes:

- mode 1 (with a 2048-byte data block size)
- mode 2 (with 2352-byte data blocks)
- audio

Since Apple systems request 512-byte data blocks, and our drivers interpret the data correctly in either case, the differences between mode 1 and mode 2 are indistinguishable to the user.

..TIL02595-AppleCD_SC-General_Description_Discontinued.pdf

The AppleCD SC can be used with both the Apple II and Macintosh families, using the appropriate supplied software drivers. It can also be used on an AppleShare File Server to provide network access to workstations.

AppleCD SC: Specifications (Discontinued)

Revised: 9/13/93
Security: Everyone

AppleCD SC: Specifications (Discontinued)

Article Created: 1 March 1989
This article last reviewed: 25 January 1991

Physical Dimensions

depth	266 mm	(10.47 inches)
width	246 mm	(9.69 inches)
height	84 mm	(3.31 inches)
weight	4.0 kg	(8.8 lbs)

(the drive mechanism alone is 146 x 212 x 62mm)

Disc Specifications

recording surfaces	1
disc diameter	120 mm
disc center hole	15 mm
thickness	1.2 mm
track pitch	1.6 microns (15,875 tracks per inch)
scanning velocity	1.2 - 1.4 meters per second
rotation speed	Varies over radius, approximately 530 to 230 rpm
latency (average)	approximately 55 to 130 milliseconds
blocks per rotation	8.4 to 19.5 variable

Data Specifications

Data capacity	550 MB, mode 1 630 MB, mode 2
number of blocks/disc	270,000
data per block	2048 bytes, mode 1 2336 bytes, mode 2
address description	minutes, seconds, frames
playing time	1 hour

Data Streaming Rates

blocks per second	75 blocks per second
user bytes per second	153.6K, mode 1
	175.2K, mode 2
SCSI bus transfer rate	800K per second

Access Time

Average	Less than 600 milliseconds (500ms, typical)
Maximum (First to last block)	Less than 1.2 seconds (800ms, typical)

Modes Supported

CD-ROM modes 1 and 2
CD-Audio

Environmental

Noise (maximum)
Drive on (seek or non-seek) <46 dB(A)

Temperature

Operating Temperature	+10 degrees C to +40 degrees C
Storage (6 months)	-30 degrees C to +50 degrees C
Transit (72 hours)	-30 degrees C to +55 degrees C

Humidity Classified as Class 1 equipment

Power Requirements

AC Input (US and Canada) 120V AC +/- 10%, 58 to 62 Hz
AC Input (Universal) 100/120/200/220/240V AC +/- 10%, 48 to 62 Hz
The drive cannot be powered directly by a 12V power supply.

Power Consumption

Drive on 40 watts

Interface

SCSI expansion ports 50-pin connector

(NOTE: The AppleCD SC does not perform oversampling of the audio section.)

Three Compact Disc Formats Described

Revised: 3/30/94
Security: Everyone

Three Compact Disc Formats Described

=====

This article last reviewed: 22 October 1990

The AppleCD SC supports the following compact disc formats:

- the Red Book
- the Yellow Book
- High Sierra/ISO 9660
- HFS

Red Book

The first standard developed in the compact disc industry is known as the "Red Book" standard. It was proposed by Philips and Sony, and describes the CD hardware, form factors, and media specifications. Today, the Red Book is followed throughout the industry for CD-Audio. It also forms the basis for the Yellow Book and High Sierra standards discussed below.

The Red Book defines the way bit patterns are written to the compact disc, provides for synchronization bytes, and supports error correction within each "frame", or packet, of data. The overhead needed to accomplish this means that each frame, which represents 192 data bits (24 bytes), requires 588 channel bits on the compact disc.

The CD-Audio data correction algorithm is called the Cross Interleave Reed-Solomon Correction (CIRC) method and is intended to correct large runs of data that may be unreadable due to laser error or a defective or scratched disc. In this process, frames are interleaved and error checking is performed on the sum of this data. Error bursts of up to 450 data bytes in length can be corrected using this technique. CIRC recovery used on compact discs results in an observed error rate of less than one unrecoverable error in 2,000 discs.

CD-Audio reads digital sound samples at 44.1 KHz per second. With 16 bits per sample and two channels, the player reads 1,411,200 bits per second. Compact discs are capable of storing up to 75 minutes of sound per disc,

although 60 minutes is commonly quoted as CD-Audio's capacity.

Yellow Book

Philips and Sony also collaborated on the Yellow Book standard, which defines CD-ROM data addressing, and supplies a richer error detection and correction algorithm than is found on CD-Audio.

CD-ROM data is organized into blocks with 98 24-byte frames in each. Of the 2352 data bytes in each block, 2048 bytes, or 2 Kbytes, is user data. The compact disc player reads 75 blocks each second. At 75 minutes of playing time (the same as CD-Audio), the CD-ROM can hold 660 Mbytes of data. However, 60 minutes is generally used as the standard capacity, which equates to 550 Mbytes of CD-ROM data per disc.

Additional error detection and error correction (EDC/ECC) defined by the Yellow Book provide extra accuracy on CD-ROM discs. Each 2K data block is accompanied by 276 bytes used in a second layer of CIRC. Together with the Red Book's first layer of error correction, the algorithms result in an undetectable error rate of only 1 bit in 2 quadrillion discs.

High Sierra

In 1986, Apple was one of a number of interested parties that gathered at the High Sierra hotel, near Lake Tahoe, to come to a agreement on CD-ROM file formats. The result was a proposal, known as the High Sierra standard, which defines a hierarchical file system to be used on a CD-ROM.

The High Sierra file system is written with compact disc characteristics in mind. For example, it does not include instructions to delete or write to files, since compact discs are read-only media. High Sierra also addresses the relatively slow seek time of the compact disc by specifying a path table on each volume. When a host computer requests a file from a High Sierra CD, a single seek will give the location of the disc's file, no matter how deeply it may be buried in nested folders. This directory may also be cached within the CPU, so that the host computer can immediately request the compact disc player to move to the file on the CD.

High Sierra is system-independent, so that a disk (pressed with information conforming to High Sierra) could be conveniently read on Apple II, Macintosh, IBM PC, and other computers. All essential file data is written in palindrome format -- data is written twice: once as "high byte, low byte", and again as "low byte, high byte".

High Sierra discs are limited to no more than eight levels of "folders", and file names of no more than 31 characters.

NOTE: Prior to being adopted by the ISO Committee, ISO 9660 was know as High Sierra. Although some minor changes were made to High Sierra during the ISO standardizing process, Apple's driver will enable you to read CD-ROM discs pressed in either format. The two format names are often used interchangeably.

CD-ROM: Glossary of Terms

Revised: 3/1/88
Security: Everyone

CD-ROM: Glossary of Terms

=====

This article last reviewed: 29 February 1988

CD-Audio

Industry standard for compact disc player hardware, compact disc media, and level 1 error correction and detection. Also known as the Red Book. Supported by AppleCD SC.

CD-I (Compact Disc - Interactive)

Proposal that includes a compact disc file structure definition. Also known as the Green Book.

CD-ROM (Compact Disc - Read-Only Media)

Defines data storage and error detection and correction on compact disk. Also known as the Yellow Book. Supported by AppleCD SC.

CD-V (Compact Disc - Video)

Definition for full-motion video on NTSC. Supports 200MB of CD-ROM information and five minutes of full-motion video in Laserdisk format.

CLV (Constant Linear Velocity)

Used on storage devices (among them compact discs) to maintain one speed at which data passes by the head. Requires varying rotation speeds as the radius of the track changes.

CVD (Compact Video Disc)

Full-motion video definition from SOCS Research.

DVI (Digital Video Interface)

..TIL02599-CD-ROM-Glossary_of_Terms.pdf

Definition for a full hour of video on compact disc at 30 frames per second.
Supports CD-ROM.

Green Book

See CD-I.

High Sierra

Hierarchical file structure definition for CD-ROM. System-independent.
Supported by AppleCD SC.

Land

Flat area on inner surface of compact disc. Reflects laser light back to
sensor. Represents data value "1".

Laser (Light Amplification by Stimulated Emission of Radiation)

Produces coherent light by exciting molecules of pure chemical substance.

Mastering

The process of creating the "golden" disc, which is then used to create
copies for use in compact disc manufacture.

Optical media

Any data storage device that operates using light to retrieve and/or write
data to storage medium. Typically uses laser to produce light. Compact disc
is one type of optical media.

Pit

"Bump" on inner surface of compact disc. Scatters laser light. Represents
data value "0".

Premastering

The process of adding error detection and correction bytes to user data.
Done prior to mastering disc.

Red Book

See CD-Audio.

WORM (Write Once - Read Many)

Removable optical media which accept new data only once. Data can be read
many times. Not compatible with compact discs.

Yellow Book

See CD-ROM.

Apple II Workstation Card: Product Information (2/97)

Revised: 3/3/97
Security: Everyone

Apple II Workstation Card: Product Information (2/97)

=====

Article Created: 01 March 1988
Article Reviewed/Updated: 28 February 1997

TOPIC -----

This article describes the Apple II Workstation Card.

DISCUSSION -----

The Apple II Workstation Card provides an AppleTalk interface for the enhanced Apple IIe computer. It makes the Apple IIe an AppleTalk node on a LocalTalk network.

Hardware

The card has its own 65C02 processor, ROM, RAM, and a custom PAL chip. The card attaches to a connector module housing two Mini-8 serial ports. One of these ports supports AppleTalk, the other emulates a Super Serial Card.

The card can be installed in any Apple IIe slot except for slot 3 (the additional 64K of RAM on the Extended 80-Column card is assigned to slot 3, making it unavailable). Slot 7 is the usual choice for the Workstation Card.

The red and green LEDs indicate only that the card has passed an internal diagnostic, and do not indicate that the network interface is active.

The upper Mini-8 connector (PORT A) supports either the AppleTalk interface or a Super Serial interface. The lower Mini-8 connector (PORT B) supports only the serial interface.

Software

The Apple IIe Workstation Card contains AppleTalk code in ROM, code to allow printing over the network, printing at the workstation, and starting up over the network. The Apple IIe Workstation Card can start up either from a local disk, or remotely over the network from a startup server running on a file server.

Local Startup

When the workstation starts up from a local device, the card makes itself look like a Super Serial Card, with special ID bytes to indicate that it is actually an Apple II Workstation Card.

Network Startup

The card emulates a Disk II drive on power up to enable network startup, and, if in the highest number slot (normal practice) downloads the operating system from a network startup server, if available.

In addition, either of these other two methods can be used to start up over a network:

- Use the PR# command specifying the card's slot and hold down the Open Apple key while pressing Return. (Issuing the PR# command and pressing Return without pressing the Open Apple key causes printing to take place.)
- Using a BOOT call also causes the startup process to take place.

Printing Over the Network

The printing task begins when you issue a PR# command from the workstation. The application program sends print data out through the SSC entry points as defined by the PR# command. The card captures the stream of characters to be printed, because it appears to be a normal Super Serial Card in a slot and sends it to the selected printer or spooler.

Only ProDOS applications are supported on the network using the card. An important feature of the card is that it does not require the use of main memory, because most applications use all or almost all of Apple IIe memory (including "reserved" areas).

Aristotle: Apple II Menu Management Software

Revised: 5/31/89
Security: Everyone

Aristotle: Apple II Menu Management Software

=====

This article last reviewed: 29 February 1988

Overview

Aristotle is Apple's Apple II menu manager, a user software interface. Aristotle was designed primarily for the classroom, but you can put it to work in any school, administrative, or business area. With Aristotle, users simply select from a menu, where without it they had to type complex path and prefix sequences.

With Aristotle, the network or workstation manager can control and simplify the user interface by setting up a menu of selectable applications for each student, class, and teacher. The individual can use the network server with all the network access, control, and storage needs, while enjoying the simple user interface.

Installation

Aristotle Menu Manager software is installed on an AppleShare File Server v2.0. Aristotle's software comprises the Teacher (Menu Manager) and the Student (Menu User).

The Menu Manager (or Teacher) is used only to set up the student menu selections. The AppleShare Network Administrator and the Aristotle Menu Manager (they can be the same person) work together to create specific user menus.

With Apple II Utilities, the Aristotle software is loaded from a 3.5" disk drive on a workstation (any server workstation will do) into an AppleShare File Server v2.0.

Hardware Requirements

For an Apple IIe to be a Menu Manager workstation, it must have:

- an Apple II mouse and mouse interface card
- Apple II Memory Expansion card with 256K
- the Apple II workstation card.

An Apple IIGS system can act as a Manager if the IIGS software is present in the server, and the IIGS has at least 1MB on the Apple IIGS Memory Card, to provide the needed storage area for the overlays. It is recommended that the application already be loaded into the server, so that the manager can actually see the specific path name.

Using Aristotle

After logging on, a student

1. sees a list of the teachers who have selected that student to be in any of their menus,
2. chooses a teacher,
3. see the class list (again, specific menu selections) for that teacher,
4. selects a class, and
5. chooses an application, which launches it.

Once the application is launched, quitting it returns the student to the Application menu, allowing selection of another (or the same) application.

There is no escape from the loop, and students don't have to memorize (or refer to) any ProDOS path or prefix for anything other than their own files.

Apple II: Turn Off Line Feed When Using 3rd Party Printers

Revised: 5/31/89

Apple II: Turn Off Line Feed When Using 3rd Party Printers

=====

This article last reviewed: 19 February 1988

Third party dot matrix impact printers need to receive a Carriage Return within a control code in order to set print densities to certain values.

Unfortunately, when a CR is sent from an Apple IIc or a Super Serial Card, the interface automatically sends a Line Feed as well. Temporarily turning off the interface's automatic LF can be done with a Control-I K. To turn automatic LF back on, use Control-I L.

The problem is, these characters may be ignored by the interface and sent to the printer instead.

There are other ways of getting back to default conditions on a printer, such as sending a 'RESET' code, or turning off/turning on the printer. The problem with this is that some printers take a long time resetting. This can be noisy and sometimes very time consuming, especially if done often.

Here is why this happens (and a solution):

The Super Serial Card (and its Apple IIc serial port equivalent) will forward control characters if preceded by a Control-I. While it's true that Control-I is the command to send to set up specific functions, in order to send the command to the card without it forwarding said command to the printer, you must send the command preceded by TWO Control-I's.

- The first Control-I alerts the card that a command it needs to operate on is forthcoming.
- The second Control-I is used by the card, along with its attendant characters, as the command string, to change interface functions.

If what follows the first Control-I is not a control character, the card (firmware) forwards the next characters to the printer.

TIFF (Tag Image File Format): Specifications (7 of 7)

Revised: 3/22/88
Security: Everyone

TIFF (Tag Image File Format): Specifications (7 of 7)

=====

This article last reviewed: 12 February 1988

6. Examples

A binary image from a paint program might contain only SubfileType, ImageWidth, ImageLength, StripOffsets, and PhotometricInterpretation fields.

A typical line art scan might require that XResolution and YResolution be added to the above list.

7. Private Fields

An organization may wish to store with the image file information that is meaningful only to that organization. Tags numbered 32768 or higher are reserved for that purpose. Upon request, the administrator will allocate and register a block of private tags for an organization, to avoid possible conflicts with other organizations.

Private enumerated values can be accommodated in a similar fashion. Enumeration constants numbered 32768 or higher are reserved for private usage. Upon request, the administrator will allocate and register a block of enumerated values for a particular field, to avoid possible conflicts.

Tags and values which are allocated in the private number range are not prohibited from being included in a future revision of this specification. Several such instances can be found in this revision.

8. A List of Possible Future Enhancements

In the future TIFF will very likely be expanded to support more compression schemes, more photometric schemes, color lookup tables, and non-rectangular images. Please refer all questions regarding enhancements to TIFF to the contacts listed at the beginning of the document. Written submissions should be in Microsoft Windows Write format, to ensure timely and error-free

incorporation into the specification.

LaserWriter: Possible Causes of Curved/Skewed "Straight" Lines

=====

This article last reviewed: 15 February 1988

If a line drawn as a straight vertical lines on the Macintosh's screen is not a perfectly vertical line when printed on a LaserWriter, it may be due to:

- the type of paper stock being used
- a problem with the paper feed assembly
- a faulty laser scanner unit

If the line is straight but not perfectly vertical when printed, it may be due to the skew adjustment.

HyperCard: How To Install Desk Accessories In Stacks

=====

Article Created: 14 March 1988
Article Last Reviewed: 27 May 1992
Article Last Updated: 27 May 1992

Note: The following information applies only to system software versions earlier than 7.0. Under System 7, the Font/DA Mover is no longer used, and desk accessories are opened just like regular applications.

TOPIC -----

I received a desk accessory (DA) that needs to be installed directly into a HyperCard stack. How can I do this?

DISCUSSION -----

Developers sometimes ship a desk accessory for use specifically with their software products, so that the DA is available in the Apple menu only while running their products. It's possible, for example, to install desk accessories into HyperCard. While in Font/DA Mover, hold down the Option key while clicking the Open button. This will allow you to select and open HyperCard. Copy the DA normally once the program is open in one of Font/DA Mover's windows. The DA is now installed in HyperCard's resource fork, and it will show up in the Apple menu whenever HyperCard is running.

HyperCard:How It Launches & Quits Applications Under MultiFinder

=====

Article Created: 22 March 1988
Article Last Reviewed: 6 April 1992
Article Last Updated: 6 April 1992

TOPIC -----

The following discusses the method in which HyperCard 1.2 launches and quits applications when running under MultiFinder.

DISCUSSION -----

Under the Finder, when you launch an application from HyperCard then quit that application, the "resume" system message is sent and you return to HyperCard instead of to the Finder.

MultiFinder, on the other hand, patches the "launch" ROM call and handles it before HyperCard is passed the launch information. And HyperCard is not informed when you quit from the application. Consequently, you don't always return to HyperCard when you quit from the application that was launched from HyperCard.

MultiFinder: How To Set The Launch Order Of Applications

=====

Article Created: 15 February 1988
Article Last Reviewed: 9 August 1991
Article Last Updated: 9 August 1991

TOPIC -----

I don't understand how MultiFinder determines the order for launching applications. I open them in the order I prefer and use Set Startup. However, they still open in random order.

DISCUSSION -----

When using 6.0.x, the order in which you open applications before using Set Startup doesn't determine launch order at startup. Study these three steps:

- 1) Open three applications in the order A-B-C.
- 2) Choose Set Startup and select Opened Applications and DAs.
- 3) Restart the system.

If you were to do this, MultiFinder may open the applications in B-C-A order, or in any other sequence.

The order the applications launch is by most-recently-modified application first, next-most-recently-modified application second, and so on. There's a way to ensure that applications open in a particular order.

- 1) Open all applications you want launched at startup.
- 2) From the Apple Menu, choose the application you want to open last.
- 3) Make some kind of change within the application: type some text or draw some graphics.

- 4) From the Apple Menu, select the application you want to open next to last.
- 5) Make some kind of change within this application.
- 6) Repeat steps 3 through 5 for each application.
- 7) Choose Set Startup and select Opened Applications and DAs.

As an example, open MacWrite, MacPaint, and Excel. Excel works best when launched first; MacWrite and MacPaint don't care. So, to make Excel launch first, MacPaint second, and MacWrite third.

- 1) From the Apple menu, choose MacWrite; type some text and press Return a few times.
- 2) From the Apple Menu, choose MacPaint; draw a circle or a box.
- 3) From the Apple menu, choose Excel; type some numbers and press Return a few times.
- 4) From the Apple menu, choose the Finder.
- 5) Choose Set Startup and select Open Applications and DAs.
- 6) Restart your system. Excel should open first, MacPaint second, and MacWrite third.

Revision Notes

This release of the TIFF specification has been given a Revision number. It is really the fourth major revision, so the Revision number was set to 4.0.

Abstract

This document describes TIFF, a tag based file format that is designed to promote the interchange of digital image data.

The fields were defined primarily with desktop publishing and related applications in mind, although it is conceivable that other sorts of imaging applications may find TIFF to be useful.

The general scenario for which TIFF was invented assumes that applications software for scanning or painting creates a TIFF file, which can then be read and incorporated into a "document" or "publication" by an application such as a desktop publishing package.

The intent of TIFF is to organize and codify existing practice with respect to the definition and usage of "desktop" digital data, not to blaze new paths or promote unproven techniques. Yet a very high priority has been given to structuring the data in such a way as to minimize the pain of future additions. TIFF was designed to be a very extensible interchange format.

TIFF is not a printer language or page description language, nor is it intended to be a general document interchange standard. It may be useful as is for some image editing applications, but is probably inappropriate for -- and would thus need to be translated into some intermediate data structures by -- other image editing applications. The primary design goal was to provide a rich environment within which the exchange of image data between application programs can be accomplished. This richness is required in order to take advantage of the varying capabilities of scanners and similar devices. TIFF is therefore designed to be a superset of existing image file formats for "desktop" scanners (and paint programs and anything else that produces images with pixels in them) and will be enhanced on a continuing basis as new capabilities arise.

Although TIFF is claimed to be in some sense a rich format, it can easily be used for simple scanners and applications as well, since the application developer need only be concerned with the capabilities that he requires. The mechanisms for accomplishing this goal are discussed in the next section.

TIFF is intended to be independent of specific operating systems, filing systems, compilers, and processors. The only significant assumption is that the storage medium supports something like a "file," defined as a sequence of 8-bit bytes, where the bytes are numbered from 0 to N. The largest possible TIFF file is 2**32 bytes. Since pointers (byte offsets) are used liberally, a TIFF file is most easily read from a random access device,

although it is possible to read and write TIFF files on sequential media such as magnetic tape.

The recommended MS-DOS file extension for TIFF files is ".TIF". The recommended Macintosh filetype is "TIFF". Conventions in other computing environments have not yet been established.

Parity Checking: Why Apple Doesn't Use It

Revised: 6/17/92
Security: Everyone

Parity Checking: Why Apple Doesn't Use It

=====

Article Created:
Article Last Reviewed: 1 June 1992
Article Last Updated: 1 June 1992

Background: Why Parity Checking Came About

Parity checking first became an issue when computer manufacturers started using early DRAM (Dynamic Random Access Memory) technologies. These chips were quite unreliable, and since they were relatively small (1KB - 4KB), vendors had to use a large number of them (increasing the odds of failure) to produce a system with a useful amount of memory. In that environment, parity checking ensured that if a soft error (one that can't be reproduced) occurred, a user would not be able to save potentially corrupted data back to disk.

Apple's Approach: Increased DRAM Reliability

Apple took a different approach and worked with its chip vendors to increase DRAM reliability. The result has been that each new generation of DRAMs seems to be twice as reliable as the previous generation. The mean time between soft errors doubles, even though the chip capacity quadruples. Thus, for a given amount of memory, each new generation of DRAMs has eight times the reliability of its predecessor.

As a practical matter, the reliability of current computer technology is not gated by the reliability of the hardware: system and application software fail (and corrupt data) several orders of magnitude more often than the hardware on which they run. There are also several good engineering reasons why Apple doesn't use parity checking:

- Cost. In addition to requiring more RAM, additional circuitry must be added to the logic board to detect parity errors.
- No Significant Reliability Improvement. The 256K DRAMs we currently use typically experience soft errors every 1,000,000 hours per device, or once every 3.5 years for a 1MB Macintosh system.

- No Real Protection. How a system reacts to a parity error is at least as important as checking for one in the first place. Most MS-DOS PCs react poorly and crash the system when they detect a parity error, threatening both the user's files and file system.

Apple is not alone in these conclusions. While early versions of IBM's 360 series of mainframes used parity checking, more recent versions have moved towards "error correcting code" to maintain system integrity.

System Reliability and System Performance

The Macintosh already checks its memory for hard failures as a part of the startup sequence. Apple could also adopt an error correction scheme similar to that used in most of today's mainframes, and totally protect the user against single bit soft errors. Essentially, this approach adds three bits to each byte so that the system can detect an error and correct it. This approach is expensive, and would require substantial changes to both our operating system and hardware.

More important, both parity checking and error correction code would impact the overall performance of future Macintosh systems. In essence, both these schemes require that the hardware detect a soft error in less time than it takes the microprocessor to execute an instruction. As Apple moves to faster microprocessors, less time is available for the hardware to test all of the memory during each instruction cycle. Given the choice between investing in faster, more reliable DRAM technology (and hence, faster systems) or investing in a parity checking algorithm that constrains system performance, most users would prefer the former. For customers who require parity checking, Apple does offer a model of the Macintosh IIci with parity checking.

Macintosh II: How to Sample Stereo Sound

Revised: 7/2/92
Security: Everyone

Macintosh II: How to Sample Stereo Sound

=====

Article Created: 16 February 1988
Article Last Reviewed: 29 June 1992
Article Last Updated:

TOPIC -----

How do I sample stereo sound with my Macintosh II?

DISCUSSION -----

The Farallon MacRecorder sound sampler allows you to sample stereo sounds on the Macintosh II.

Use the MacRecorder to record the left channel, then separately record the right channel. To record both channels simultaneously, connect two MacRecorders.

MacRecorder comes with a program called SoundEdit that allows for sound mixing, special effects (echo, flanger, noise, etc.), editing sampled sounds, and more.

Note: the Macintosh II internal speaker plays only the left channel -- to hear stereo sound, you must add external speakers.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Macintosh: How NFNT Format Differs From FONT Format

Revised: 11/5/91
Security: Everyone

Macintosh: How NFNT Format Differs From FONT Format

=====

Article Created: 22 March 1988
Article Last Reviewed: 5 November 1991
Article Last Updated: 5 November 1991

TOPIC -----

DISCUSSION -----

Macintosh fonts are stored as resources, either as type FONT or type NFNT. The two font types have the same format. NFNT (New FoNT) is new to the 128K ROM version of the Font Manager (64K ROMs ignore resources of type NFNT).

NFNT allows for many more fonts.

An NFNT resource type can also be used to mask all but plain fonts from appearing in a font menu. In this way, the system resource file can contain Times, Times Italic, Times Bold, and Times Bold Italic, yet only Times appears in the Font menu. (The user would need to choose Italic from the Style menu.)

For more information, see the Font Manager chapter of Inside Macintosh, Volume V.

TIFF (Tag Image File Format): Specifications (2 of 7)

Revised: 3/22/88
Security: Everyone

TIFF (Tag Image File Format): Specifications (2 of 7)

=====

This article last reviewed: 12 February 1988

1. Conformance

Many of the application programs that read the contents of TIFF image files will not support all of the features described in this document. In some cases, little more than the default options will be supported. It is up to each organization to determine the costs and benefits associated with different levels of conformity. Therefore, claims of conformity to this specification should be interpreted with a certain amount of caution.

It follows that the usage of this specification does not preclude the need for coordination between image file writers and image file readers. It is up to the application designer that initially writes a file in this format to verify that the desired file options are supported by the applications that will read the file.

2. Structure

In TIFF, individual fields are identified with a unique tag. This allows particular fields to be present or absent from the file as required by the application.

Some TIFF files will have only a few fields in them; others will have many. Software that creates TIFF files should write out as many fields as it believes will be meaningful and useful (and no more). Software that reads TIFF files should do the best it can with the fields that it finds there.

There are many ways in which a tag-oriented file format scheme can be implemented. TIFF uses the following approach:

There are three main parts to a TIFF file. First is a short image file header. Next is a directory of all the fields that are to be found in this file. Finally, we have the data for the fields.

3. Header and Directory

A TIFF file begins with a small amount of positionally defined data, containing the following information:

Bytes 0-1:

The first word of the file serves to specify the byte order used within the file. The currently defined values are:

"II" (hex 4949)

"MM" (hex 4D4D)

In the "II" format, byte order is always from least significant to most significant, for both 16-bit and 32-bit integers.

In the "MM" format, byte order is always from most significant to least significant, for both 16-bit and 32-bit integers.

In both formats, character strings are stored into sequential byte locations.

It is certainly not required that all applications software be able to handle both formats. It should be apparent which is the native format for a particular machine.

Bytes 2-3:

The second word of the file is the TIFF version number. This number shouldn't change. This document describes Version 42, so 42 (2A in hex) should be stored in this word.

Bytes 4-7:

This long word contains the offset (in bytes) of the first Image File Directory. The directory may be at any location in the file after the header but must begin on a word boundary.

(The term "byte offset" is always used in this document to refer to a location with respect to the beginning of the file. The first byte of the file has an offset of 0.)

An IFD consists of a 2-byte count of the number of entries (i.e., the number of fields), followed by a sequence of 12-byte field entries, followed by a 4-byte offset of the next Image File Directory (or 0 if none). Each 12-byte field entry has the following format:

Bytes 0-1 contain the Tag for the field. Bytes 2-3 contain the field Type. Bytes 4-7 contain the Length ("Count" might have been a better term) of the field. Bytes 8-11 contain the file offset (in bytes) of the Value for the field. The Value is expected to begin on a word boundary; the corresponding file offset will thus be an even number.

The entries in an IFD must be sorted in ascending order by Tag. Note that this is not the order in which the fields are described in this document. The Values to which directory entries point need not be in any particular order in the file.

If the Value fits within 4 bytes, the Offset is interpreted to contain the Value instead of pointing to the Value, to save a little time and space. If the Value is less than 4 bytes, it is left-justified. Whether or not it fits within 4 bytes can be determined by looking at the Type and Length of the field.

The Length part is specified in terms of the data type. A single 16-bit word (SHORT) has a Length of 1, not 2, for example. The data types and their lengths are described below:

- 1 = BYTE. 8-bit unsigned integer.
- 2 = ASCII. 8-bit bytes that store ASCII codes; the last byte must be null.
- 3 = SHORT. A 16-bit (2-byte) unsigned integer.
- 4 = LONG. A 32-bit (4-byte) unsigned integer.
- 5 = RATIONAL. Two LONGs: the first represents the numerator of a fraction, the second the denominator.

The value of the Length part of an ASCII field entry includes the null. If padding is necessary, the Length does not include the pad byte.

The reader should check the type to ensure that it is what he expects. TIFF currently allows more than 1 valid type for a given field. For example, ImageWidth and ImageLength were specified as having type SHORT. Very large images with more than 64k rows or columns are possible with some devices even now. Rather than add parallel LONG tags for these fields, it is cleaner to allow both SHORT and LONG for ImageWidth and similar fields. Writers of TIFF files are, however, encouraged to use the default type values as indicated in this document to insure compatibility with existing TIFF reader applications.

Note that there may be more than one IFD. Each IFD is said to define a "subfile." One potential use of subsequent subfiles is to describe a "sub-image" that is somehow related to the main image, such as a reduced resolution or "screen resolution" image. Another use is to represent multiple "page" images -- for example, a facsimile document requiring more than one page. Subsequent IFDs will in general contain many of the same fields as the first IFD but will usually point to or contain different values for those fields.

TIFF (Tag Image File Format): Specifications (3 of 7)

Revised: 3/22/88
Security: Everyone

TIFF (Tag Image File Format): Specifications (3 of 7)

=====

This article last reviewed: 12 February 1988

4. Definitions

The TIFF structure itself is not specific to imaging applications in any way. It is only the definitions of the fields themselves that jointly describe an image. Before we begin describing the fields, a few image related definitions may be useful.

An image is defined to be a rectangular array of "pixels," each of which consists of one or more "samples." With monochromatic data, we have one sample per pixel, and "sample" and "pixel" can be used interchangeably. Color data usually contains three samples per pixel, as in, for example, an RGB scheme.

5. The Fields

The following fields are defined in this version of TIFF. More will be added in future versions, if possible in such a way so as not to break old software that encounters a newer TIFF file. An attempt has been made to group related fields, although the grouping is necessarily somewhat arbitrary.

The documentation for each field contains the name of the field (quite arbitrary, but convenient), the Tag value, the field Type, the Number of Values (N) expected (per IFD, in the case of multiple subfiles), comments describing the field, and the default, if any. The default value is used if the field does not exist.

A fairly large number of fields has already been defined, and the number will grow. Please keep in mind that many common images can be described using only a handful of these fields (see the Examples section).

General Description

SubfileType
Tag = 255 (FF)
Type = SHORT
N = 1

A general indication of the kind of data that is contained in this subfile. Currently defined values are:

- 1 = full resolution image data - ImageWidth, ImageLength, and StripOffsets are required fields.
- 2 = reduced resolution image data - ImageWidth, ImageLength, and StripOffsets are required fields. It is further assumed that a reduced resolution image is a reduced version of the entire extent of the corresponding full resolution data.
- 3 = Single page of a multi-page image (see the PageNumber tag description).

If your kind of image data doesn't fit nicely into either description, contact either Aldus or Microsoft to define an additional value. Note that both image types can be found in a single TIFF file, with each subfile described by its own IFD.
No default.

Data Architecture

ImageWidth
Tag = 256 (100)
Type = SHORT
N = 1

The image's width, in pixels (X: horizontal). The number of columns in the image.
No default.

ImageLength
Tag = 257 (101)
Type = SHORT
N = 1

The image's length (height) in pixels (Y: vertical). The number of rows (sometimes described as "scan lines") in the image. ImageLength and ImageWidth refer only to how the pixels are stored in the file and do not imply anything about where the visual "top" or "left side" of the image may be. See Orientation for this information.
No default.

RowsPerStrip
Tag = 278 (116)
Type = SHORT or LONG
N = 1

The number of rows per strip. The image data is organized into strips for fast access to individual rows when the data is compressed (though this field is valid even if the data is not compressed).

Note that either SHORT or LONG values can be used to specify RowsPerStrip. SHORT values may be used for small TIFF files. It should be noted, however, that earlier TIFF specifications required LONG values and that some software may not expect SHORT values.

Default is $2^{32} - 1$, which is effectively infinity. That is, the entire image is one strip.

[StripsPerImage]

N = 1

The number of strips per image. This value is not a field, since it can be computed from two other fields, but it is convenient to give it a name in order to clarify the use of other fields. The equation to use is $\text{StripsPerImage} = (\text{ImageLength} + \text{RowsPerStrip} - 1) / \text{RowsPerStrip}$, assuming integer arithmetic.

StripOffsets

Tag = 273 (111)

Type = SHORT or LONG

N = StripsPerImage for PlanarConfiguration equal to 1.

= SamplesPerPixel * StripsPerImage for PlanarConfiguration equal to 2

For each strip, the byte offset of that strip. The offset is specified with respect to the beginning of the TIFF file. Note that this implies that each strip has a location independent of the locations of other strips. This feature may be useful for certain editing applications. This field is the only way for a reader to find the image data, and hence must exist.

Note that either SHORT or LONG values can be used to specify the strip offsets. SHORT values may be used for small TIFF files. It should be noted, however, that earlier TIFF specifications required LONG strip offsets and that some software may not expect SHORT values.
No default.

Apple IIGS Memory Expansion Cards: RAM Chip Specs & Vendors

Revised: 2/10/93
Security: Everyone

Apple IIGS Memory Expansion Cards: RAM Chip Specs & Vendors

Article Created: 22 March 1988

Article Change History

02/09/93 - UPDATED
 • Micron Technology acquired by Xceed Technologies.
04/20/88 - REVIEWED
 • Reviewed for accuracy.

The RAM chips on the memory expansion card for the Apple IIGS must be 150ns chips of 256K bits organized in 256K by 1 bit; they also must have CAS (Column Address Strobe) before RAS (Row Address Strobe) refresh.

Unless the RAM chips on the expansion board conform to these specifications, the Apple IIGS will have intermittent errors. These errors can take the form of system crashes, lock ups, memory errors, etc.

The only memory chips RECOMMENDED for use on memory expansion cards for the Apple IIGS are Apple part #334-0021. The following are among the vendors that manufacture RAM that is COMPATIBLE with the Apple IIGSS.

- Fujitsu America, Inc.	MB81256-15P
- NEC Microcomputers, Inc.	UPD41256C-15
- Texas Instruments	TMS4256-15NL
- Mitsubishi Electronics	M5M4256AP-15
- Hitachi	HM50256P-15
- OKI Semiconductor	M41256-15
- Xceed Technologies	MT1259-15
- Samsung	KM41256AP-15
- Motorola	MCM6256BP-15
- Toshiba America	TMM41256P-15

NOTE: This list is not complete and is intended for reference only.

To locate a vendor's address and phone numbers, use the vendor name as a search

string.

HyperCard Handles: Q and A

Revised: 6/24/90
Security: Everyone

HyperCard Handles: Q and A

=====

This article last reviewed: 17 February 1988

Q. When in my XFCN, I'm given a handle to the parameter string. Is the handle locked? Should I lock it if I de-reference it? Is it OK to unlock it? Can I operate on the string in memory and just pass back the handle that was given to me?

A. Never assume a handle to be in a certain state -- locked, unlocked, purgable, unpurgable, etc. If you wish to ensure the handle is in a known state, call HGetState to retrieve the current state of the handle. The HLock and HUnlock procedures allow you to set the flag as you like.

At the end of your routine, reset the flag as it was, by passing back the original flag.

This technique should be used if you wish to modify the state bits of any handle not created by your program.

Q. How do I treat a handle that really belongs to another process?

A. If a handle belongs to another process, don't call HUnlock if locked, or HPurge if unpurgable flag is set -- HyperCard has set those flags that way for a reason, and they shouldn't be tampered with.

Q. When I set the return handle, does HyperCard dispose of it for me?

A. HyperCard disposes of the handle when you're through with it.

ImageWriter II & LQ: How To Get Them Into Hex Mode

Revised: 3/22/88
Security: Everyone

ImageWriter II & LQ: How To Get Them Into Hex Mode

=====

This article last reviewed: 17 February 1988

Putting the ImageWriter II Into Hex Mode

The only way to put the ImageWriter II into hex mode is to hold down the select button while powering it on. Sending an escape-c afterwards should restore (software reset) the printer to its standard instruction set. (Alternatively, you write a program to convert the ASCII to hex, then print.)

If the ImageWriter II Drops into Hex Mode

After a logic error in the printer, the ImageWriter II sometimes prints in hex -- usually random garbage. If a printer consistently "drops" into hex mode, consider exchanging its logic board.

Putting the ImageWriter LQ Into Hex Mode

The ImageWriter LQ can be placed in hex mode via the software command:

esc,6

Your data will then print in hex until the printer is powered off, or until you send a software reset, esc-c.

Apple II Family: Using With LaserWriter (2/97)

=====

Article Created: 22 March 1988
Article Reviewed/Updated: 17 February 1997

TOPIC -----

This article discusses using a LaserWriter printer with the Apple II family of computers.

DISCUSSION -----

A LaserWriter can be connected to any Apple II containing a Super Serial Card, or the serial ports (modem port and printer port) in an Apple IIc or Apple IIGS.

This is made possible by setting the serial interface to use XON/XOFF protocol using one of the following two methods.

1st Method

Send the following code exactly as shown. The Super Serial Card must be in communications mode (jumper block set to "modem"), because print mode (jumper block set to "terminal") doesn't support XON/XOFF.

Apple IIc/IIGS printer port:	Control-I X E
Apple IIc/IIGS modem port:	Control-A X E
Super Serial Card:	Control-I X

- Control-I (or Control-A) tells the firmware that you are sending a character to act on.

- The X tells the firmware to use XON/XOFF protocol.

- The E says 'Enable the function designated by the next printable character.'

2nd Method

Set up the LaserWriter for DTR handshake (requires version 2 or greater of the LaserWriter ROMs). This can be done by sending the following code segment to the LaserWriter with the switch set to 9600:

```
serverdict begin 0 exitserver
statusdict begin
25 9600 7 setsccbatch
end
```

This sets the 25-pin connector to 9600 baud, DTR flow control, no parity. Substituting 9 for 25 sets the 9-pin connector to the same parameters. This change is written into EEROM, and remains as what is called a persistent parameter until changed back. To change the printer back to XON/XOFF, send this code segment:

```
serverdict begin 0 exitserver
statusdict begin
25 9600 3 setsccbatch
end
```

Macintosh: How To Bypass Internal Hard Disk At Startup (5/96)

Revised: 5/23/96
Security: Everyone

Macintosh: How To Bypass Internal Hard Disk At Startup (5/96)

Article Created: 23 February 1988
Article Reviewed/Updated: 23 May 1996

TOPIC -----

How can I bypass the internal hard disk at startup? I know the Macintosh will boot from a floppy disk if I insert one. But what if I want to boot from an external hard disk or CD-ROM?

DISCUSSION -----

There's a way to start up your system from the next bootable SCSI device in the chain (an external hard disk, CD-ROM, and so on), or floppy disk, while keeping the internal hard disk off line. There's no way to start a Macintosh without also powering on the internal hard disk.

Note: Any Apple system (Macintosh IIci or newer) equipped with an Apple compatible CD-ROM drive (that works with Apple's CD-ROM driver) can startup from the Install Me First CD-ROM. For detailed instructions reference the article, "Macintosh: Starting From Floppy or CD-ROM Disk," Article 0018059 in the Tech Info Library.

Examples -- When You Need to Bypass the Hard Disk

You might want to bypass the hard disk when trying out some new software of dubious origin on a floppy disk. It's also useful in a situation where the proper System Enabler is no longer in your internal hard disk System Folder, but is in the System Folder of some other device in the SCSI chain.

How To Do It

Hold down four (yes, four!) keys while you start up:

Command-Shift-Option-Delete

In the case of a compact Macintosh, with its power switch in the back of

the main unit, you'll have to either get someone to help you, or use a pencil clamped in your teeth as a "third hand."

The system starts up from the floppy disk or the next bootable SCSI device in the chain beginning with ID 6, and the internal hard disk doesn't even appear on the desktop.

Article Change History

23 May 1996 - Added reference to booting from CD-ROM drive

21 May 1993 - REVISED

- To include an example, and to mention CD-ROMs and other devices that may be present in a SCSI chain.

List Of Disk Recovery Tools For The Macintosh (9/94)

Revised: 2/17/97
Security: Everyone

List Of Disk Recovery Tools For The Macintosh (9/94)

Article Created: 22 March 1988
Article Reviewed/Updated: 21 September 1994

TOPIC -----

Here is a list of disk recovery tools, with some comments.

DISCUSSION -----

1st Aid Kit, by Datawatch Corp. (formerly 1stAid Software)

Audience Level: Novice to Intermediate.

A general trouble-shooting package, including file and disk recovery. The main feature of the system is its 300-page manual. This manual describes many of the errors a user may receive, including printing/Chooser errors, memory problems, and Finder messages (such as, "Trash could not be emptied,") and lists procedures to solve that problem. It also includes detailed information on what can go wrong with a disk, and how 1st Aid Kit can fix it. The manual is fully indexed and cross-referenced.

It includes a software program intended to aid in the recovery and identification of lost or deleted files, and also contains capabilities for extracting files from crashed disks. It does NOT alter the original crashed disk, or offer sector editing. This program contains extensive on-line help.

The File menu includes: Eject All, Archive volume Info, Check for Uninitialized Disk, Erase Deleted Files, Initialize, Help, and Quit.

The Edit menu includes: Undo, Cut, Copy, Paste, Clear, and Help.

The Disk Repair menu includes: Diagnose & Recover, Salvage Files by Tags, Zero Out Bad Sectors, Fix Boot Blocks, and Help.

The File Repair menu includes: Work on File, Undelete Files, Rejoin File, and Help.

Disk First Aid v7.2, by Apple Computer, Inc.

Audience Level: Novice to Expert

Disk First Aid is a utility which verifies the directory structure of any hierarchical file system (HFS) based storage volume. Many hard disk drives, floppy disk and compact disk (CD) drives are examples of HFS-based storage volumes.

If imperfections are found within a volume, Disk First Aid can be used as a "first step" to repair the defects/ if a volume has suffered several corruption other utility programs or repair methods may need to be used.

Disk First Aid 7.2 (released August 1993) checks for and repairs following volume attributes:

- Disk volume
- Extent B-tree
- Extent File
- Catalog B-tree
- Catalog File
- Catalog Hierarchy
- Volume Info
- Search for locked volume name

You can save the results of a verification or repair scan as a TeachText (text) document.

Disk First Aid cannot scan for deleted or trashed files or folders on a volume. There are several third party products which perform these tasks, however.

FEdit, by MacMaster Systems

Audience Level: Intermediate to Expert

This is a Block Editing system for HFS and MFS floppies and hard disks.

Version 1.0.5 lets you open either a file or disk volume for examining and editing. You can read sectors in their raw form, or view the VIB, Boot Blocks, and file headers in an interpreted form. You can perform sequential and multiple read/writes using multiple block buffers. Editing and display can be set to Hex or ASCII. File options allow you to open either the Data or Resource fork, and even exchange them. Search capabilities let you enter either Hex or ASCII data, and will even search the sector tags if present. Special options let you create or delete files, set the end of a file, recreate the volume bit map, analyze the state of file fragmentation, and recover deleted files. Support for HFS file recovery and display is not fully implemented.

Version 2.0 now contains support for full HFS recovery, including the use of sector tags for file recovery and low-level SCSI routines.

MacTools, by Central Point Software, Inc.

(Disk Editor and File Utility included with Copy II Mac)

Audience Level: Intermediate to Expert

This program includes: Copy files/disk, rename files/disk, verify that a file/disk has no errors, view and edit file and disk sectors, format a disk, delete a file, lock and unlock files, make file visible or invisible to the Finder, protect or unprotect files from normal copying, change the startup application on a disk to something other than the Finder, recover deleted files and repair some damaged disk, look or change the information stored on disk, print a list of files on the disk.

MacTools offers two methods of files recovery. The first uses the tag information on floppies and hard disks that support them. The second involves an INIT program that saves information about deleted files into a data file as they are deleted. A routine in MacTools can then be used to extract that information and recover the deleted files.

MacTools also offers a limited form of disk recovery. If a disk cannot be mounted (the Finder displays the "This disk is damaged" dialog box,) you can use MacTools to mount the disk, erasing the directory at the same time. If the disk supports tags, you can use MacTools to recover them. If you don't want to erase the directory, you can use a disk editor provided with MacTools to examine and patch the disk.

MacZap, by Micro Analyst

Audience Level: Intermediate to Expert

This is a three-part disk and memory utility. It contains many programs that can be used to recover some damaged files and disks, to compare disks, analyze disk structure, and make back-up copies of most disks.

Version 5.0 includes Disk Clinic, a program that helps diagnose a disk and recommends recovery procedures.

Norton Utilities v2.0.3, by Symantec

Audience Level: Novice to Expert

Data recovery, disk repair and backup Macintosh Plus or larger; 2 MB of RAM (3 MB for System 7); hard disk drive; System 6.0.4 or later.

Norton Utilities for Macintosh combines and enhances the features from two products: SUM II and Norton Utilities. The combination of these two products results in a utility software package that offers fully integrated advanced disk repair and recovery, automatic backup, data security, productivity tools and

system enhancements in one informative, easy-to-use product. Version 2.0.3 goes deeper to recover lost or damaged data in a wider variety of circumstances, and the Norton Disk Doctor diagnoses and repairs damaged hard disks and floppies automatically with a single click of the mouse. Norton Utilities allows users to protect valuable data and make day-to-day functions a breeze.

Public Utilities by 5th Generation Systems (bought by Symantec)

Audience Level: Novice to Expert

Public Utilities is a disk recovery utility for Macintosh hard drives. It contains a prevention monitor that keeps the hard drive from crashing.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Article Change History:

21 Sep 1994 - Reformatted and corrected utility names.
16 Sep 1993 - Added Disk First Aid, Norton Utilities, and Public Utilities
26 Jul 1993 - Company title updated from Datawatch to Datawatch Corp.

A/UX: Program Portability (Machine Independence)

Revised: 9/16/92
Security: Everyone

A/UX: Program Portability (Machine Independence)

=====

Article Created: 1 March 1988

Article Change History

08/27/92 - REVIEWED
o For technical accuracy.

TOPIC -----

Any A/UX application is potentially portable (machine independent) to other System V.2 platforms.

DISCUSSION -----

In other words, you should be able to compile and run any A/UX application under System V.2, as long as the A/UX application does NOT either interact with hardware or make library calls to the Apple enhancements to System V -- such as Toolbox, rpc services, BNet (sockets), etc.

The reverse is also true: because A/UX has passed SVVS (System V Validation Suite), any System V program that follows the SVID (System V Interface Definition) will run under A/UX.

A/UX: How to Improve File Access Speed (6/93)

Revised: 8/18/93
Security: Everyone

A/UX: How to Improve File Access Speed (6/93)

Article Created: 25 March 1988
Article Reviewed/Updated: 18 August 1993

TOPIC -----

How can I improve file access speed under A/UX?

DISCUSSION -----

There is no way to increase the physical access speed of a SCSI drive while running under A/UX. However, there are several things you can do with software and hardware additions to increase file-access performance:

- Increasing RAM to more than 8MB is a good beginning. The more the system can store in memory, the less frequently it needs to access the disk for the next call of the same blocks.
- For systems with 8MB, bring A/UX up single-user, then run these commands:

```
# kconfig -n /unix
NBUF=2500
NINODE=600
NFILE=400
<control-d>
# sync
# sync
# sync
# reboot
```

- Add a second hard disk and place the swap there, along with any directories that don't see high activity. That way, the CPU can search for files on the primarily disk, while searching the swap for others.
- Add as much free space as possible by deleting all files not really necessary for your system -- man pages, source, networking, games, and so on.

For more information, search under: "A/UX" and "space", "free", or "minimum".

CS/2200 Terminal Emulator: Macintosh to Wang Connectivity

=====

This article last reviewed: 25 February 1988

If you need a Wang CS/2200 terminal emulator package, Mac2200 from Vermont Software supports:

- cutting and pasting
- Desk Accessories
- access to all features provided by the 32 function keys on the CS/2200 keyboard.

This package also supports Switcher and Hayes compatible modems.

Mac2200 is compatible with the Macintosh 512KE, Macintosh Plus, Macintosh SE, and Macintosh II. It requires a Wang 2200/MVP, LVP, SVP, MicroVP, or CS system with a 2236 MXD or MXE terminal controller.

For more information, search under: "Vermont Software".

SCSI Cables: Extenders And Pinouts (4/94)

=====

Article Created: 1 March 1988
Article Reviewed/Updated: 5 April 1994

TOPIC -----

How many SCSI Cable Extenders can I use on my SCSI chain?

DISCUSSION -----

With the use of multiple SCSI Cable Extenders, a SCSI bus can safely cover a distance of up to 21 feet (seven meters) between two devices, such as a CPU and hard drive. Typically, extender cables are 1 meter in length.

Both the Peripheral Interface Cable and the Cable Extender have a straight-through pin configuration (1-1, 2-2, 3-3, etc.), though pins 10, 12-15, 17, 35-37, 39, 40, and 42 are not connected.

Article Change History:
5 April 1994 - Revised format, clarified issue, added info on pins not connected.

LaserWriter IINTX: How To Use IBM Fonts (8/95)

Revised: 8/23/95
Security: Everyone

LaserWriter IINTX: How To Use IBM Fonts (8/95)

=====
Article Created: 22 March 1988
Article Reviewed/Updated 22 August 1995

TOPIC -----
Can I download my IBM fonts to the hard disk attached to my LaserWriter IINTX?

DISCUSSION -----

You can't download IBM fonts to a LaserWriter IINTX hard disk: the IBM downloader currently downloads only to RAM.

However, screen fonts common to both Macintosh AND a given IBM can be downloaded from Macintosh and then accessed through the IBM.

An example: if you download the "Garamond" font from a Macintosh to the LaserWriter IINTX hard disk, you can then access that font from an IBM, if "Garamond" is an installed screen font on that IBM.

Comparison of LaserJet Plus and IINTX LaserJet Plus Emulation

Revised: 3/4/90
Security: Everyone

Comparison of LaserJet Plus and IINTX LaserJet Plus Emulation

=====

This article last reviewed: 8 March 1988

Adobe Systems has performed tests comparing LaserWriter IINTX and LaserJet Plus. Their finding is that a LaserWriter IINTX in LaserJet Plus emulation mode is generally faster than a LaserJet Plus.

Although you can't download bitmapped LaserJet Plus Fonts to the LaserWriter IINTX, you CAN use any of the PostScript Fonts, including downloaded fonts. Unlike the LaserJet fonts, PostScript Fonts can be scaled, resulting in much more precise output.

Security: Everyone

Apple IIGS: Using LaserWriters via AppleTalk

=====

This article last reviewed: 15 March 1988

The Apple IIGS can print to the PostScript devices LaserWriter, LaserWriter Plus, LaserWriter IINT, and LaserWriter IINTX. Because the Apple IIGS ImageWriter Emulator isn't compatible with the System Tools 5.0 Laser Prep files for the Macintosh, the IIGS must download its Prep file and reinitialize the printer if you're using the newer Prep files on the Macintosh.

Because the Apple IIGS' QuickDraw II differs from Macintosh QuickDraw, there is currently no driver for the Apple IIGS that would let it print to the LaserWriter IISC, as SCSI/QuickDraw device; and Apple has no plans for one.

The IIGS Chooser is being modified for use with the ImageWriter LQ over AppleTalk.

LaserWriter II: Removing the "Protective Cover"

=====

This article last reviewed: 22 March 1988

The LaserWriter II's installation instructions refer to a "protective cover" that must be removed. This is the styrofoam that is taped across the opening of the controller board slot. This styrofoam is to keep debris out of the controller board area during shipment.

The antistatic insulator taped to the bottom panel of the LaserWriter II "engine" should NOT be removed. It will cause no problems when left in place.

AppleWorks Spreadsheet: Displayed Numbers Are Sometimes Rounded

=====

This article last reviewed: 16 March 1988

The AppleWorks spreadsheet displays numbers as close to the calculated value as it can, given the display format chosen by the user. Even if the user specifies that only two places are displayed, AppleWorks still calculates it up to nine digits, and can display up to nine digits (seven digits past the decimal point).

For example, the calculation $.07 * 2.5$ results in .175, but if the display is set to just two decimal places, the number displayed is .18. Any subsequent calculations will be based on the actual value .175, not on the displayed value of .18. AppleWorks calculates to all significant digits and displays according to display values set by the user.

HyperCard: Specifying the Answer Command's Default Button

=====

This article last reviewed: 15 March 1988

HyperCard's Answer command produces a dialog box with up to three buttons, where the rightmost button is the default.

To specify which of the buttons is to be the default button, make it the last definition in the list. (There is no way to avoid having a default button.)

At this point, we know of no XCMDs or XFCNs that customize the dialog box to include more text or buttons. It would be much easier to trap the "answer" message and have it execute an XFCN instead.

ImageWriter II: A Gentle Way to Make Ditto Masters

=====

This article last reviewed: 15 March 1988

Schools have asked if it was possible to make ditto masters with the ImageWriter II. Apple has suggested removing the ribbon from the printer and moving the forms thickness lever back to the third or fourth position. This is supposed to help keep the print head from damaging the fragile master. The problem is that this method keeps the printer in single color-mode which, in most cases, doesn't transfer enough ink to the master -- not from the non-existent ribbon, but by the impact of the wires -- to produce a good image. This is due, in part, to the density of the actual top page of the ditto master itself and the size of the wires in the head of the ImageWriter II.

Here is another method -- one that will improve the quality of the ditto master:

1. Remove the ribbon from an ImageWriter II color ribbon cartridge.
2. Insert this empty cartridge in the printer. This will close the color micro-switch on the carrier assembly, and fool the printer into believing it has a color ribbon installed.
3. Through your software, tell the printer, via control codes, to print in either Orange, Green, or Purple. Because these three colors are normally created by making two passes with two different colors, and the printer believes it has a color ribbon installed, the print density will be doubled, improving the quality of the ditto master.

Without the color ribbon installed, and with a color selected that requires two passes to create, the printer will effectively be in double strike mode, which is not a selectable mode otherwise. With double strike, the dots are almost completely re-struck, which produces a better image while not abusing the ditto master itself. (Boldface could be used but that mode does not overstrike dots completely, rather it strikes a dot that partially overlays the previous dot, which produces a broader image that may not be acceptable

..TIL02714-ImageWriter_II-A_Gentle_Way_to_Make_Ditto_Masters_(TA37880).pdf

on ditto masters.)

LaserWriter IISC: Can Print Any Screen Font

Revised: 3/31/88
Security: Everyone

LaserWriter IISC: Can Print Any Screen Font

=====

This article last reviewed: 23 March 1988

The LaserWriter IISC can print any bit-mapped screen font -- including those you create yourself using programs such as Fontastic Plus -- not just the ones supplied with the system.

For optimum printing resolution, it's best to have the 4x font available, but not essential. If the 4x font isn't available, the Font Manager will look for the next best font to scale:

- a font twice the size of the desired four times font
- a font half the size of the desired four times font
- the next larger font
- the next smaller font or the display font.

If the 4x font isn't available, it is advisable to choose Text Smoothing in Page Setup.

Using the Altsys program Fontographer, you can convert any Altsys PostScript font into a rough bit-map screen font. We'd recommend then using the Altsys program Fontastic Plus to edit the rough screen font into something more suited for printing.

For more information on Fontographer or Fontastic, search the Tech Info Library for Altsys.

System Software 5.0 Installer Works Only On Its Own System File

Revised: 5/10/89
Security: Everyone

System Software 5.0 Installer Works Only On Its Own System File

=====

This article last reviewed: 23 March 1988

The System Software 5.0 Installer works only with System files that are exact copies of the System file included on the Installer disk.

When you use the Installer to install the System folder onto a disk, only the files and resources necessary for the Macintosh system you are installing for are copied to that disk. There are more resources in the System file on the Installer disk than the System file it installs on another disk. The error

error -192, Can't find Scrapbook file for Macintosh xx Installer

is generated when the Installer tries to find a particular resource (the Scrapbook in this example) that is not present in the "installed" System file.

The only workaround is to "drag copy" the System file from the Installer disk to your hard disk. The Installer should then function correctly.

Japanese ImageWriter II is Universal Model

=====

This article last reviewed: 23 March 1988

The ImageWriter II sold in Japan is the universal model. It supports:

100 VAC +/- 10%, and 50/60Hz
120 VAC +/- 10%, and 50/60Hz
140 VAC +/- 10%, and 50/60Hz
200 VAC +/- 10%, and 50/60Hz
220 VAC +/- 10%, and 50/60Hz
240 VAC +/- 10%, and 50/60Hz

If the line voltage drops below these levels, the printer will not function properly. A step-up transformer or a voltage stabilizer should be used under other conditions.

The ImageWriter II sold in the U.S. requires 120 volts (+/- 10%), and 60Hz.

This information is also found on page 85 of the ImageWriter II Owner's Manual, and in the Tech Info Library article titled "ImageWriter II: Spec Sheet."

Apple MIDI: How To Make It SMPTE Compatible

Revised: 9/16/88
Security: Everyone

Apple MIDI: How To Make It SMPTE Compatible

=====

This article last reviewed: 9 September 1988

The Apple MIDI Interface does not transmit or receive the SMPTE (Society of Motion Picture and Television Engineers) Time Code data stream. SMPTE Time Code is transmitted over separate cabling, most often by way of 1/4-inch (sometimes RCA) plugs.

This type of connection is not supported on the Apple MIDI Interface. Also, the Apple MIDI Interface would need a microprocessor to accommodate SMPTE Time Code. The Apple MIDI Interface does not contain a microprocessor.

Certain pieces of hardware can accept SMPTE Time Code and, in turn, generate MIDI Time Code (MTC). MTC is imbedded into the standard MIDI data stream, and thus, can be transmitted via MIDI cables. Should MTC be in the data stream when arriving at the Apple MIDI Interface, MTC will be passed with no changes. Programs that understand MTC may then perform their operations according to MTC timing data.

AppleLine Not Responding May Be Cable Problem

Revised: 3/31/88
Security: Everyone

AppleLine Not Responding May Be Cable Problem

=====

This article last reviewed: 2 March 1988

If AppleLine is not responding, you may be using the wrong cable.

IF you have set up your Macintosh with a terminal program
(such as MacTerminal) and an AppleLine in the following manner:

- AppleLine is connected to the Macintosh by an Apple IIe to ImageWriter II cable and gender changer. Both are connected to a 3174 cluster controller.
- After the AppleLine warms up, the yellow and green lights alternately flash, whether the AppleLine is connected or not.
- MacTerminal has been configured as specified in the manual.

AND, when the AppleLine Supervisor document is opened and you press Shift-Enter and Return, NOTHING HAPPENS -- whether the AppleLine is connected to the cluster controller or not

THEN, your problem is probably a wrong cable.

To connect an AppleLine to a Macintosh Plus, Macintosh SE, or Macintosh II, you must use one of these:

- the A2C0311 590-0331-B Tan
- the A2C0312 590-0555-A Platinum cable

These cables have a DIN 8 at one end and a 25 pin on the other.

Security: Everyone

Cleaning Equipment That May Have Asbestos Contamination

=====

This article last reviewed: 28 April 1988

Some Apple computer users, due to asbestos contamination at their building sites, have asked about cleaning potentially contaminated hardware.

Depending upon the extent of the asbestos contamination, each internal assembly or part of the equipment may need to be disassembled and cleaned. A QUALIFIED ASBESTOS SCREENING CONTRACTOR OR AGENCY MUST MAKE THIS DETERMINATION.

Each piece of equipment must be opened to obtain dust samples for the tests. After the testing, if the equipment needs to be decontaminated, you MUST work with a qualified Apple dealer service tech for the cleaning.

The cleaning of the equipment may be as simple as using a vacuum to remove the asbestos dust, or as difficult as washing down each assembly with de-ionized water and then drying each assembly. In either case, care must be taken to follow ESD (Electrostatic Discharge) procedures.

AppleTalk and IBM Type 1 Cabling

Revised: 11/2/88
Security: Everyone

AppleTalk and IBM Type 1 Cabling

=====

This article last reviewed: 3 March 1988

Some users have asked about running AppleTalk over IBM Type 1 Cabling.

While Apple does not know of anyone currently running such a configuration, IBM Type 1 cable is two sets of twisted pairs 22-AWG with a braided shield, so there is no reason why one pair of the twisted pairs could not be used for an AppleTalk network.

The connectors for the Type 1 cable, however, might be a problem. One possible solution would be to use PhoneNet connection modules and attach RJ11 phone connectors to the Type 1 cable.

MPW 2.0.x and Long LaserWriter Printouts: Font Problem

=====

Article Created: 31 March 1988
Article Last Reviewed: 5 November 1991
Article Last Updated: 5 November 1991

If you are printing from MPW v2.0.1 or v2.0.2 on your Macintosh to a LaserWriter Plus, and using something previous to System Software version 7.0, you may experience the following problem on long printouts: the listing will spontaneously switch to a bitmapped version of the font. Here are some possible solutions.

You may be experiencing a collision in memory between the System file (and its fonts) and the document being printed. This problem depends on several variables -- the amount of memory installed in the system, the number of applications loaded into memory, how large a RAM cache has been set, whether background printing turned on, etc.

To isolate the problem, remove as many variables as possible. For example:

- use the Finder rather than MultiFinder for pre-System 7.0 software.
- turn off the RAM Cache from the Control Panel.
- do not use Background printing.

Other possible problem areas include: bad parameter RAM, a corrupted font resource, a corrupted System file, or a corrupted printer driver.

Reinstall the system software and drivers and then try running under the finder, NOT under MultiFinder, when printing from MPW.

Another solution would be to upgrade to MPW 3.0 or higher.

Laserwriter IISC Requires System V4.3

=====

This article last reviewed: 3 March 1988

If you are having trouble printing to the Laserwriter IISC from AppleLink, and you have the correct driver to print from other software, you may be using the wrong System file.

You MUST use System version 4.3 with the LaserWriter IISC.

Identifying Apple IIGS Keyboards

Revised: 3/31/88
Security: Everyone

Identifying Apple IIGS Keyboards

=====

This article last reviewed: 10 March 1988

If you are developing applications with the Apple IIGS, you may need to be able to identify which keyboard is being used: the ADB or the Apple IIe (that is, the logic board connector for the keyboard located at site J13).

Since the Apple IIGS was primarily designed to use an ADB keyboard, the only way to determine if a keyboard is connected to J13 and not the ADB bus is to make an assumption. The assumption will be made by a response -- or lack of response -- from the AsyncADBReceive (\$0D09) Toolbox routine.

The AsyncADBReceive routine will NOT receive a keyboard response if there is no ADB keyboard present.

(NOTE: A wrong assumption could be made at this point -- for instance, with an Apple IIGS with its ADB keyboard disconnected. The application being constructed should ask if the user is ACTUALLY using an Apple IIe which has been upgraded to an Apple IIGS.)

Complete information about the AsyncADBReceive routine can be found in the Apple IIGS Toolbox Reference (ISBN #0-201-17746-3): Volume 1, Section 3, page 14.

American Macintosh Works With International ImageWriter

=====

Article Created: 10 March 1988
Article Reviewed/Updated: 17 November 1994

TOPIC -----

Can I use an ImageWriter made outside of the United States with my Macintosh computer?

DISCUSSION -----

A domestic Macintosh may be used with an international version of the ImageWriter (such as the Japanese or European version).

Even though the power specifications change from country to country, or region to region, the RS232 and AppleTalk standards are universal throughout the world.

No Guarantee On Domestic Apple Equipment's Foreign Operation

=====

This article last reviewed: 10 March 1988

Apple makes no guarantee of successful operation of Apple equipment when it is used outside of the equipment specifications -- including its operation in a foreign country with different voltage levels, etc.

Even though a piece of equipment may APPEAR to function correctly when operating outside of the specifications, unexpected results may be encountered due to additional variables. These variables include the number of peripheral cards installed in the system, and fluctuations in line voltage.

Such variables make it impossible for us to guarantee that, for instance, a domestic Macintosh II will correctly function at 85-90 volts in Japan.

HyperCard: Video Disk Searches Must Be Slowed On a Macintosh II

=====

This article last reviewed: 10 March 1988

Some users have found that the Macintosh II, working from HyperCard, cannot search and then play a laser disk video selection with a script like the following (which seems like it should work, and does with a Macintosh SE):

```
On MouseUp
  video search, 10600
  video play, till, 10900
End MouseUp
```

The reason is that, unlike the SE, the Macintosh II is TOO FAST. If the laser disk receives messages too closely together, it won't accept the second command.

This script should solve the problem:

```
On MouseUp
  video search, 10600
  wait 30
  video play, till, 10900
End MouseUp
```

The "wait 30" is 30 clicks -- a half-second wait that gives the laser disk time to react.

Printing Serial PostScript To LaserWriter: Dictionary Is Problem

Revised: 3/31/88
Security: Everyone

Printing Serial PostScript To LaserWriter: Dictionary Is Problem

=====

This article last reviewed: 11 March 1988

Some users have experienced a problem printing a PostScript file generated on the Macintosh through a serial device (such as a Sun 3/280) to a LaserWriter: there is no printout.

Generally, PostScript files generated on a Macintosh are "encapsulated" PostScript. Encapsulated PostScript files require that a dictionary of definitions be downloaded to the printer prior to the document being sent -- otherwise, the PostScript interpreter within the LaserWriter will not understand the abbreviated PostScript code, and the document will not be printed.

When printing a file directly to a LaserWriter from a Macintosh, the Macintosh usually verifies first that the correct dictionary of definitions has been sent to the LaserWriter. If the dictionary of definitions in the LaserWriter is NOT correct, then a header file (Laser Prep) is added to the beginning of the print job that prepares the printer for the forthcoming print job.

However, when the printer is placed into the serial mode, the dictionary of definitions is NOT retained, and MUST BE APPENDED to the beginning of each print job. This is done by holding down the Command and K keys when printing the Macintosh document. The same file may be generated without the header information by holding down the Command and F keys when printing.

The only exception to this is if the Macintosh file was saved as a FULL PostScript format (perhaps from an application like Adobe Illustrator.) In this case, because there are no abbreviations, there is no need to download a dictionary of definitions.

Some users have asked about UNIX training courses.

There is no one course that will teach UNIX, and learning UNIX takes years of concentrated work on a UNIX system. However, there are different types of courses that suit different areas or levels where assistance is needed.

Here are some recommendations from Apple engineers on a few of the UNIX courses with which they are familiar. This is a VERY LIMITED sample, and does not reflect Apple Computer's official position on ANY courses, listed or unlisted.

DISCUSSION -----

Some users have asked about UNIX training courses.

There is no one course that will teach UNIX, and learning UNIX takes years of concentrated work on a UNIX system. However, there are different types of courses that suit different areas or levels where assistance is needed.

Here are some recommendations from Apple engineers on a few of the UNIX courses with which they are familiar. This is a VERY LIMITED sample, and does not reflect Apple Computer's official position on ANY courses, listed or unlisted.

AT&T Computer Systems Training

Reservations and information: (800) 247-1212

Classes are currently held in New Jersey, Illinois, Georgia, Ohio, and Northern and Southern California. Shorter tutorials are also offered in Massachusetts, Virginia, New Jersey, Colorado, and Northern and Southern California.

These offer a wide curriculum for different levels of expertise.
(NOTE: The more technical classes require proof of a source license.)

Some Apple engineers have recommended the Internals, System Administration, and/or Shell programming classes for field engineers who are required to support A/UX and have some basic user knowledge of UNIX. Introductory-level classes are also available, as well as training tapes.

User Training Services Group

Jim Corcoran (415) 322-0460

This is an interactive audio digital cassette tape training that offers a low - medium level of expertise in UNIX basics. They also have a smaller curriculum aimed at beginning UNIX users. Monthly rentals of the tape courses are also available.

Computer Technology Group

Reservations and information: (800) 323-UNIX

Classes are currently held in Massachusetts, Chicago, Texas, Canada, England, Washington D.C, and Northern and Southern California.

These classes, and the tape-trainings, are a more accessible but less rigorous course than, for instance, the AT&T offering.

Gawain Group and Jim Joyce's UNIX BookStore

Registration and information: (415) 626-7581

This organization offers courses customized for your location and semi-regular classes held in Toronto and Northern California. The trainers are experienced in the industry and often are the authors of the code.

The Bookstore also offers a most extensive collection of UNIX and C programming books, with bulk discounts available. They also offer short evaluations that might assist you in selecting reading material to augment or substitute for your training.

Three UNIX resources Apple engineers have recommended are:

- "The Design of the UNIX Operating System" by Maurice Bach
(A "Bible" offering a comprehensive overview and a detailed study of internals)
- "UNIX in a Nutshell" from O'Reilly and Associates
(An easy to read reference to augment the bulky UNIX manuals)
- "UNIX Communications" by the Waite Group
(An easy-to-follow guide the communications utilities built into UNIX)

ImageWriter LQ: Odd Test Print May Be Bad Ribbon Installation

Revised: 11/22/91
Security: Everyone

ImageWriter LQ: Odd Test Print May Be Bad Ribbon Installation

=====

This article last reviewed: 16 March 1988

If you have an ImageWriter LQ, you may get a strange test print of varying print density which is caused by an incorrectly installed black print ribbon.

If you get a test print with a black ribbon that shows four lines of light print followed by three lines of dark print, the pattern continuing as long as the test print is generated (the ribbon may also move vertically), here is the reason for the problem -- and the solution.

The black ribbon has a small tab on the left-hand end which actuates a micro-switch located in the left-front of the printer near the control panel. This indicates to the printer that it does not have a color ribbon installed (the color ribbon does not have this tab.)

When a COLOR ribbon is installed the micro-switch is not depressed, which sets in motion the various color functions of the printer, such as ribbon vertical motion, overstrike for certain colors, etc.

When the BLACK ribbon is installed, the micro-switch should be depressed, setting the printer into single-color mode.

The characteristics of a color test print are such that four lines are printed in single colors and three lines are generated with overlaid colors. With a color ribbon installed this will result in a color sequence as follows:

- Black, Yellow, Red, Blue, Orange, Green, Purple (the last three are the overlaid colors.)

However, if the black ribbon is installed but the micro-switch is NOT depressed, the printer believes it is in color mode and will generate a test print accordingly. This will result in four lines of light print (printer thinks it is printing single colors and does a single pass with

the print head) and three lines of dark print (printer thinks it is printing overlaid colors and does a double pass with the print head, moving the ribbon vertically as needed to access the second color.)

If you have this problem, make sure the black ribbon is correctly installed in the printer. Correct installation will depress the micro-switch and set the printer in single color mode, which will generate a test print of uniform density.

Part Available For Using ImageWriter II And LQ Overseas

Revised: 11/10/88
Security: Everyone

Part Available For Using ImageWriter II And LQ Overseas

=====

This article last reviewed: 10 November 1988

Domestic 110V ImageWriter II and ImageWriter LQ printers can be used on voltages greater than 110V.

One solution is to use a step-down transformer. Unfortunately, with this method you sacrifice some horizontal and vertical print registration, and force the internal DC stepper motors to run hotter, thus becoming unreliable in a shorter period of time than normal. Apple does NOT recommend or support this method.

A better solution is to use a transformer/voltage switch assembly (Apple Service Part #915-0029). With the installation of this part, an ImageWriter II can be converted from 110V to a universal printer (which be altered to suit power supplies of different voltages.) This switch assembly contains a built-in selector switch, and is designed for an operating range of 100V to 240V, and a frequency range of 48 to 62 Hertz.

The catch is that this particular part is currently not sold domestically (US and Canada,) but only abroad. The #915-0029 transformer/voltage switch assembly is only installed in printers expected to be sold in areas of the world where the operating frequency is in the 48 to 62 Hertz range. However, a consumer CAN request that an international service provider sell them this part.

The transformer/voltage switch assembly is the ONLY part that differs from a 110V printer. It is included in all International-manufactured printers. The transformer assembly used in 110V printers works properly in the operating range of 58 to 62 Hertz only.

(NOTE: Part #915-0029 is for ImageWriter II ONLY. The universal transformer/voltage switch assembly for the ImageWriter LQ is Apple Part #915-0031.)

Most printers sold outside of the United States and Canada are equipped

with the universal, or selectable, power supply, therefore no change -- other than switch position -- is required. Once the printer is converted, no other hardware (such as a step-down transformer) is required.

Here are the frequency operating ranges of ImageWriter II and ImageWriter LQ printers:

- Domestic Units 110V units @ 58 - 62 Hertz
- International Units 110V to 240V units @ 48 - 62 Hertz

Networks With Mac 512Ks Shouldn't Use LaserWriter 5.0 or 5.1

Revised: 11/4/91
Security: Everyone

Networks With Mac 512Ks Shouldn't Use LaserWriter 5.0 or 5.1

=====

Article Created: 31 March 1988
Article Last Reviewed: 4 November 1991
Article Last Updated: 4 November 1991

TOPIC -----

This article describes issues with networking Macintosh 512K machines to a LaserWriter in which newer Macintoshes are also networked.

DISCUSSION -----

If you have a multi-Macintosh network, you may have compatibility problems between the new versions of the LaserWriter print drivers and older versions of system software. These are the new print drivers:

- Version 5.0 LaserWriter printer driver, currently being shipped with Macintosh system software
- Version 5.1, which is being shipped with the new LaserWriter II printers, and includes some problem fixes.

Unfortunately, the revision of the LaserWriter drivers for the new printers has resulted in a NEW problem, which affects their compatibility with Macintosh 512K system software.

When the new LaserWriter drivers are running on the LAST supported system software for the Macintosh 512K (System 3.2 and 3.3 with Finder 5.3 and 5.4 respectively), problems are created on networks that are running with both Macintosh 512K systems and 1MB Macintosh systems (such as Macintosh Plus, SE, or II).

If users of the Macintosh Plus, SE, or II install either of the new drivers named above on their systems, this will create a conflict with Macintosh 512K users who use an older version of the LaserWriter Prep file.

In other words, if you have a network that includes both Macintosh 512K and other Macintosh systems, NO user on that network should upgrade to version 5.0 or 5.1 drivers. Otherwise, if some users upgrade you will have to re-initialize the LaserWriter every time use of the printer passes from Macintosh 512K users -- who are using pre-5.1 prep file and driver -- to users of the Macintosh Plus (or newer) who have upgraded to print drivers 5.0 or 5.1 on a hard disk.

The new LaserWriter II family of printers are compatible with previous versions of the printer drivers. However, network users should continue using the same versions of print resources they have been using until the compatibility problems have been solved.

Don't Rely On Network Events To Signify Completed Operations

Revised: 3/31/88
Security: Everyone

Don't Rely On "Network Events" To Signify Completed Operations

=====

This article last reviewed: 22 March 1988

You should not rely on "network events" to signify when an operation is completed. Network events may be purged from the event queue if it overflows, thus preventing the application from ever receiving them.

In general, you should avoid using anything other than disk-inserted or device driver events: although disk-inserted and device driver events don't have any higher priority than network events, they are much less likely to get removed from the queue because of a queue overflow. (Network events have this purging problem because multiple ATP requests may complete simultaneously, generating lots of events.)

NOTE: Another major reason not to use network events is because Apple can't guarantee to support them in the future.

It is not necessary to find alternatives to disk or driver events.

Most applications do not need to respond to disk-inserted events. By the time a disk-inserted event reaches the application, the system has already attempted to mount the volume. Most applications use Standard File, which does the response to disk-inserted events for you.

NOTE: If your application DOES need to react to disk-inserted events, it should receive this event in the regular fashion, as described in the "Event Manager" chapter of "Inside Macintosh" (page I-241, Apple Part #030-1277-A).

Also, applications usually don't have to respond to device driver events, either; in most cases, you will use higher level managers. For example, most applications depend on the File Manager, rather than the Disk Driver. Another example: the Sound Driver allows you to make a call to SoundDone to find out if an asynchronous sound is finished.

In the case of device drivers, when an asynchronous call is made you can

poll the ioResult field of the parameter block to see if the call has completed. (This field is set to 1 when the call is made.) Control is returned to the application immediately, even though the call hasn't necessarily completed. The ioResult field receives the actual result code on completion of the call, so you can determine if the call has completed by periodically checking to see if ioResult is still 1.

NOTE: See the Device Manager chapter of the above-mentioned "Inside Macintosh" (page II-173) for more details.

A/UX Meets SVVS/SVID Standards

Revised: 9/14/92
Security: Everyone

A/UX Meets SVVS/SVID Standards

=====

Article Created: 31 March 1988

Article Change History

08/31/92 - REVIEWED

- For technical accuracy

TOPIC -----

A/UX and SVVS/SVID Standards

DISCUSSION -----

A/UX is SVID-compatible and SVVS Issue 1 & 2 certified.

SVID (System V Interface Definition) is a set of specifications (somewhat like manual pages), of how internal components -- such as system calls, parameters, etc. -- should look. This specification standard allows a higher degree of code portability to other machines.

SVVS (System V Validation Suite) Issue 2 is a series of programs for System V.2 that test the System V.2 porting for about 4-5 hours. If the tests are passed with no modification, the porting (in this case, A/UX) is said to be SVID-compatible.

A/UX Version 1.0 is SVID-compatible. It passes the SVVS Issue 2 certification tests. (Issue 2 is in fact the latest and only appropriate release for our system.)

(NOTE: There is a paragraph stating SVVS-conformance on the back of the cover page of the A/UX Release Notes.)

Not only does A/UX pass the standard test with no modifications required, but it also passes the optional Kernel Extensions test, which is not required for SVID-compatibility.

HyperCard Write to File Command: How To Replace Old Text

Revised: 6/24/90
Security: Everyone

HyperCard "Write to File" Command: How To Replace Old Text

=====

This article last reviewed: 24 March 1988

You may have experienced a problem with the write command in HyperCard: when you write text to an existing file, HyperCard merely appends the new text to the old, rather than replacing the existing text.

The write command causes HyperCard to copy the specified text into the specified disk file.

Here is a script that should DUPLICATE your problem. First, create a file called "test 1" with the text "ABCD" in it:

```
on mouseUp
  open file "test 1"
  write "ABCD" to file "test 1"
  close file "test 1"
end mouseUp
```

The following scripts reads the text "ABCD" from the file "test 1" and then appends "EFGH" to the file demonstrating your problem:

```
on mouseUp
  open file "test 1"
  read from file "test 1" for 4
  write "EFGH" to file "test 1"
  close file "test 1"
end mouseUp
```

Here is a script that should SOLVE your problem. This script reads the text "ABCD" from the file "test 1" and then REPLACES the text in "test 1" with the text "EFGH":

```
on mouseUp
  open file "test 1"
  read from file "test 1" for 4
```

```
    close file "test 1"  
    open file "test 1"  
    write "EFGH" to file "test 1"  
    close file "test 1"  
end mouseUp
```

The key to replacing text instead of appending text is closing the file "test 1" and then reopening the file "test 1". If you open "test 1" and read for 2 characters, then write "EFGH" to "test 1" you will get "ABEFGH" in your file. In other words, you will append text starting where the read or write statement stopped.

LaserWriter II: Fuser Temperature, Paper Speed

Revised: 5/10/89
Security: Everyone

LaserWriter II: Fuser Temperature, Paper Speed

=====

This article last reviewed: 31 March 1988

When choosing an acetate transparency for use in a LaserWriter II, it is important to consider the temperature of the printer's fuser roller and the amount of time the acetate sheet is in contract with the roller.

The temperature of the LaserWriter II fuser roller varies from:

- 329 to 356 degrees Fahrenheit
- 165 to 180 degrees centigrade

An 8.5" by 11" sheet of paper or acetate takes approximately 5.8 seconds to travel over the fuser roll. This works out to be about 1.5 inches per second.

The LaserWriter II accepts medium weight photocopier transparencies such as Scotch #503, catalog # 15921-3.

LaserWriter II: Troubleshooting & Environmental Factors (9/95)

Revised: 9/20/95
Security: Everyone

LaserWriter II: Troubleshooting & Environmental Factors (9/95)

=====

Article Created: 9 March 1988
Article Reviewed/Updated: 20 September 1995

TOPIC -----

This article describes how to troubleshoot a LaserWriter II for possible environmental conditions which could contribute to malfunctions.

DISCUSSION -----

Environmental Considerations

During the winter, if the LaserWriter II is moved from a cold area to a warm one or vice versa, condensation can occur inside the printer. This temperature change will result in image defects.

The printer should be allowed to come to room temperature before being used. This will take approximately 1 to 2 hours.

- Condensation on optical surfaces, such as the scanning mirror, lenses, or mirror assembly will result in a light print image.
- If the photosensitive drum in the toner cartridge is cold, the electrical resistance of the photosensitive layer will be high, causing image contrast problems.
- Condensation on the corona assemblies will cause corona charge leakage, resulting in poor print quality.
- Condensation on the pickup guide and feed guide plate will result in paper transport problems.

If condensation does occur, wipe the appropriate assembly or part with a dry cloth or leave the printer turned off for 10 to 20 minutes.

- Toner: During the winter, if the toner cartridge is unsealed soon

after being moved from a cold area to a warm one, condensation can occur inside the toner cartridge. This will also result in image defects. The toner cartridge should be allowed to come to room temperature before being unsealed. This will take approximately 1 to 2 hours, depending upon the temperature of the room.

Preliminary Checks

The following chart lists common problems that have simple solutions. Checking for these problems when you begin troubleshooting can save you time and effort.

Check Here First - Verify that:

- The line voltage does not vary more than 10% from the voltage shown on the serial number plate.
- The LaserWriter II is installed on a solid and level surface.
- The room temperature is kept between 10 degrees C and 32.5 degrees C.
- The relative humidity is kept between 20 and 80 percent.
- The LaserWriter II is not exposed to ammonia or other harmful gases.
- The LaserWriter II is not exposed to direct sunlight.
- The room is well ventilated.
- The LaserWriter II is not located near an open flame.
- The LaserWriter II is not located in a dusty or dirty environment.

Apple IIGS and Third Party Joysticks

Revised: 7/20/92
Security: Everyone

Apple IIGS and Third Party Joysticks

=====

Article Created: 21 March 1988
Article Last Reviewed: 17 July 1992
Article Last Updated:

PROBLEM: When using the IIGS with a joystick and the appropriate software, the "fire" button appears to be stuck on or inoperative. Replacing the logic board takes care of the problem temporarily, but within one to two weeks the system comes back in with the same symptoms. Again, replacing the logic board takes care of the problem. The option or the open-Apple key may appear to be depressed continuously.

CURE: Check the customer's joystick carefully. There are several vendors shipping joysticks which can be made compatible with other manufacturers' systems by flipping a switch on the joystick. Permanent damage to the logic board can occur if the joystick configuration switch is set to the wrong position for any length of time. Replacing the logic board will cure the problem, but be sure to instruct the customer about the cause of the damage and the importance of leaving the switch in the correct position.

This type of damage is not covered by Apple's customer or service warranty.

A/UX: Streams Defines Standard Interfaces For I/O (9/94)

=====

Article Created: 21 April 1988
Article Reviewed/Updated: 19 September 1994

TOPIC -----

What are UNIX STREAMS?

DISCUSSION -----

STREAMS defines standard interfaces for character I/O within the UNIX kernel and between the kernel and the user level. It consists of a set of structures, kernel facilities, system calls, and kernel utility routines. This collection can create, use, and dismantle a "Stream".

By connecting a selection of STREAMS components, a Stream is created -- a full-duplex processing and data transfer path between a driver in kernel space and a process in user space. The primary components of a Stream are a Stream head, a driver, and 0 or more added modules between the Stream head and driver. It is similar in concept to a Shell pipeline, except that data flow and processing are bidirectional.

STREAMS can best be described as a kernel mechanism that provides a uniform method of implementing network protocols and supporting different network media. It enables the development of application software that is independent of the underlying network services and data communication drivers. A change in medium or protocol can be accommodated through the substitution of STREAMS modules, without need for modification of the application software. It also enables the modular development of protocol software. Portability of software that performs network services is facilitated through the isolation of hardware dependencies in particular modules.

The development process is simplified by the ability to combine STREAMS modules to perform more sophisticated network services and to use the same modules over different media and in different network architectures. The STREAMS feature within A/UX is provided in addition to the existing device driver mechanisms.

In A/UX, the ADB (Apple DeskTop Bus) connection to the keyboard and mouse are supported by STREAMS I/O device drivers.

STREAMS is normally not available with UNIX System V.2. Through special licensing arrangements, a proper subset of the feature is available in A/UX.

For more information on STREAMS, see:

- AT&T's "UNIX System V STREAMS Primer"
- AT&T's "The STREAMS Programmer's Guide"
- AT&T's "System V Interface Definition"
- "Design of the UNIX Operating System" by Maurice Bach.

HD Setup: Use V1.3 Only To Restore Disk Formatted With V1.3

=====

This article last reviewed: 25 March 1988

Full-volume backups taken from a hard drive formatted with HD Setup 1.3 are incompatible for restoring to drives formatted with HD Setup version 1.5. Also, depending on the manufacture of the hard drive, the formatted disk space for the same size drive will vary by as much as 1MB to 2MB, depending on which version of HD Setup is used.

Use HD Setup 1.3 only when it's necessary to restore a backup that was taken from a drive that was FORMATTED with HD Setup 1.3.

LaserWriter: Changing Baud Rate From Software

Revised: 10/18/88
Security: Everyone

LaserWriter: Changing Baud Rate From Software

=====

This article last reviewed: 28 March 1988

To reset a LaserWriter's baud rate, even to a rate not available though the hardware DIP switches, send the following PostScript code to the LaserWriter:

```
statusdict begin 25 sccbatch exch pop
68 eq {stop} if
serverdict begin 0 exitserver
statusdict begin 25 19200 68 setsccbatch
```

This example sets the LaserWriter to 19,200 baud (using 8 data bits and DTR flow control). The change does not take effect until the end of the current job. The current job, in this case, is the PostScript code you are sending. These settings are then in effect for the duration of the next print job, and in any case will be reset within 30 seconds by the switch polling function described below. This means you must start your print job within 30 seconds in order to retain the new parameters.

If the hardware switches are used to reset the bud rate, the switches override the rate set via software.

(The test sheet will not show 19,200 because the LaserWriter defaults back to switch settings when powered up.)

Apple III QuickFile: Converting Data to Macintosh

=====

This article last reviewed: 25 March 1988

One method of moving Apple III QuickFile data to a Macintosh involves AppleWorks running on an Apple II with both a 5.25" disk drive and a 3.5" disk drive.

1. Because Apple III SOS and Apple II ProDOS are file-compatible, AppleWorks running on an Apple II can read QuickFile files from an Apple III's 5.25" disk.
2. The AppleWorks files can then be saved to a 3.5 disk.
3. A Macintosh running AFE (Apple File Exchange) can then read, via AFE's Works-to-Works transporter, the files into Microsoft Works.

LocalTalk PC Card: Version 2.0 Changes

Revised: 11/2/88
Security: Everyone

LocalTalk PC Card: Version 2.0 Changes

=====

This article last reviewed: 30 March 1988

Version 2.0 of the LocalTalk PC Card driver (ATALK.EXE) does not use the card's hardware interrupt feature. This means that the default card settings do not conflict with a COM2 serial port, and the LocalTalk PC Card can coexist with other devices using hardware interrupts.

Conflicts with other cards are unlikely because the LocalTalk PC Card driver uses relatively little used address spaces and M60 software interrupts.

No changes were made to the LocalTalk PC Card driver with respect to the DMA channels or card address range. The driver was rewritten and code optimized to take up less space, and a numeration problem was fixed.

Floppy Disks: How They Are Affected By Magnetic Fields

=====

This article last reviewed: 25 March 1988

Apple Technical Support is sometimes asked how to measure a magnet to determine if it can damage the data on diskettes. Specifications of this nature are not very informative, because there are numerous variables. Besides, not many users have instrumentation to test the magnetic field to insure the safety of the information stored on the diskette.

Some of the variables:

- the strength and proximity of the magnet
- the flux field of the magnet, which may be highly influenced by the ferrite material to which it is attached
- the age of the disk and the age of the data on the disk
- the age of the disk drive
- the condition, alignment, and cleanliness of the disk drive
- the orientation of the disk in relationship to the field

Our recommendation is always to isolate diskettes from magnetic sources, including telephones, certain monitors, even the cover of the ImageWriter I (which contains a small magnet as part the interlock switching mechanism).

Macintosh SCSI Hard Disk Drives: How Capacities Are Calculated

Revised: 9/29/90
Security: Everyone

Macintosh SCSI Hard Disk Drives: How Capacities Are Calculated

=====

This article last reviewed: 30 March 1988

After a hard disk is formatted, the Finder shows the "available" storage in kilobytes. With a given drive, this number varies with the version of HD Setup software used. For example:

Drive	HD Setup 1.3	HD Setup 1.5

HD 40SC	41,439K	39,333K
HD 80SC	76,911K	76,869K

To calculate the drive's capacity in bytes, multiply the number of kilobytes (K) by 1,024. To calculate the drive's capacity in megabytes, divide the number of kilobytes by 1,024. The capacity of the drives after being formatted with HD Setup 1.5 is:

HD 40SC	39,333K	=	40,276,992 bytes	=	38.4MB
HD 80SC	76,869K	=	78,713,856 bytes	=	75.1MB

The sizes of formatted drives varies between manufacturers, depending on the intelligence of the drive controller. Some drive controllers spare bad blocks automatically or allocate a range of blocks that can be swapped with bad blocks. It is the industry practice to quote the size of a formatted drive even though the size of the drive will vary depending on the operating system with which the drive is formatted.

Apple High-Res RGB Monitor Convergence Adjustment

=====

This article last reviewed: 26 April 1988

Because the adjustment potentiometers on the main logic board of the Apple High-Res RGB monitor can accidentally be bumped during installation, the monitor screen's vertical convergence can sometimes be off by as much as 1/8".

Adjusting the V-twist control will allow only a small section of the screen to show the correct vertical adjustment, while the top and bottom borders remain ill-adjusted. While the center of the screen may appear to be adjusted correctly, there will be distinct red-, green- and blue-shadowed images at the top and bottom of the screen. These shadowed images will appear in different sizes (i.e. the green image is larger than the red image, and the red image is larger than the blue image.)

The top and bottom sections of the screen can be adjusted correctly by adjusting the V-TOP and V-BOTTOM controls on the main logic board.

ImageWriter II High Quality Print Problem/Cure

=====

This article last reviewed: 26 April 1988

BEFORE YOU START: Familiarize yourself with the ImageWriter II Technical Procedures. Be sure to follow proper ESD procedures.

During the printing of a high quality page on an ImageWriter II, after two-thirds of a page has printed, the carriage will move quickly to the left side of the printer and then continue printing the page, with the left and right margins incorrect.

Check the following:

1. Clean the guide rail with alcohol and relubricate with new lubricant. A dirty guide rail can cause the carriage to stall momentarily, which affects the timing of the carriage motor control circuit.
2. Remove the printhead and paper guide and print the document again. (This won't print, of course, but the carriage will still move as if it was.)

If the symptom goes away, then perform the following steps:

- A. Reinstall and properly adjust the paper guide, making sure it is not rubbing on the platen.
- B. One of the pins in the printhead may not retract fast enough and will drag on the platen while the carriage is moving. Replace the printhead and perform the test again.

If the above suggestions do not solve the problem refer to the AppleLink Technical Information Library or the ImageWriter II Technical Procedures for more information on troubleshooting ImageWriter IIs.

Personal Services/PC and Personal Services/370 Described

Revised: 7/26/89
Security: Everyone

Personal Services/PC and Personal Services/370 Described

=====

This article last reviewed: 6 July 1989

Personal Services/PC is an office-oriented mail management system for the IBM PC user. It communicates with Office Systems Nodes (OSNs) using Document Interchange Architecture (DIA).

DIA provides four services:

- DDS (Document Distribution Services)
- DLS (Document Library Services)
- FTS (File Transfer Services)
- and APS (Application Processing Service)

DIA can also communicate with other PCs running PS/PC, peer-to-peer without the use of an OSN. PS/PC lets the PC user maintain a local "file cabinet" that contains items that have been sent or received. It also allows the user to develop and store distribution lists, including a "nickname" file. PS/PC requires a minimum of 224K to run on the IBM PC.

For a Macintosh to work in this environment, Personal Services/370, a mainframe version of Personal Services, must be installed on the host mainframe.

PS/370 is active in the OSN, and using the OSN, can distribute documents to other nodes using DIA as its transport and management mechanism. The "file cabinet" and lists are maintained on the mainframe. Documents transported via DIA use DCA (Document Content Architecture) as the document definition language.

Using Apple File Exchange, you can reformat a Macintosh document into DCA then distribute it to other PS nodes.

You can successfully integrate Macintosh into a DISOSS office network. Follow these basic steps:

- 1) Using the Personal Services/370 application and its MEMO format option on an MVS host, export DISOSS documents to a TSO partitioned data set.
- 2) Use a TSO file transfer program (AppleLine, Avatar, Netway, DCA, and the like) in text mode to download the document to a Macintosh.
- 3) Do the required reformatting with any Macintosh word processor.

You can just as easily upload text documents to TSO, and then import them into DISOSS using the same PS/370 MEMO option. PS/370 can also route the document to other users. A Macintosh can access PS/370 as a 3270 terminal through the file transfer package.

MacTerminal: Edit MacTerminal Documents Only With MacTerminal

Revised: 5/3/88
Security: Everyone

MacTerminal: Edit MacTerminal Documents Only With MacTerminal

=====

This article last reviewed: 31 March 1988

If you:

- create a MacTerminal document,
 - save it, then
 - use a text editor other than MacTerminal itself to make changes to the document,
- then MacTerminal may refuse to open the document, saying that the document has been modified by another application.

Here's the reason. All present versions of MacTerminal store text in the data fork of the file, and information on carriage returns in its resource fork. When MacTerminal opens the file, it compares what the resource fork states where the carriage returns should be located with where they actually exist in the data fork. If the information differs, the file will not open.

This is a known problem that will most likely be eliminated in a future version of MacTerminal. Until then, there are two workarounds:

- edit MacTerminal documents only with MacTerminal, or
- edit MacTerminal documents with another application or desk accessory, using Copy and Paste to move the information to and from MacTerminal.

Apple Tape Backup 40SC: How 1.1 Differs From 1.0

=====

This article last reviewed: 31 March 1988

Backups taken with version 1.1 of Apple Tape Backup 40SC Software often take less time than those taken with version 1.0, even with exactly the same amount of data to back up. And a backup that requires a second tape cartridge with version 1.0 may need only one cartridge with version 1.1. Here's why:

- Version 1.0 backs up all sectors from the hard disk, both used and unused sectors. This is why version 1.0 always needs a second tape cartridge to back up a 40MB disk, even if the disk held less data than the tape theoretically holds, 38.5MB.
- Version 1.1 backs up only through the last used sector. Unused sectors may still get backed up, but none that are beyond the last used sector. Version 1.1 needs a second tape cartridge only when the last used sector is beyond the 38.5MB point on the disk. If, for example, you have 30MB of data to back up, only one tape is required.

Macintosh Monitors: Eliminating Scan Lines From Video Recordings

=====

Article Created: 31 March 1988

Article Change History

9/15/92 - REVIEWED
• For technical accuracy.

TOPIC -----

A scan line sometimes rolls down the screen on video recordings of a Macintosh screen.

DISCUSSION -----

The best way to get rid of the scan line is to use a modification that lets the Macintosh accept an external composite sync. This genlocks the Macintosh screen to the camera.

One GenLock interface, for Macintosh through SE, is supplied by Digital Design Labs.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

LaserWriter IINTX: Switching Modes Using Software, 1 of 2 (2/95)

Revised: 2/21/95
Security: Everyone

LaserWriter IINTX: Switching Modes Using Software, 1 of 2 (2/95)

Article Created: 29 April 1988
Article Reviewed/Updated: 21 February 1995

TOPIC -----

It is possible to connect a LaserWriter IINTX to two devices (for example, to a Macintosh via the AppleTalk port and to another device via the serial port) and to switch between them via softswitches.

DISCUSSION -----

It is not necessary to use the DIP switches, which are not rated for large numbers of cycles. The LaserWriter IINTX checks the position of the DIP switches at regular intervals (<30 Sec) and if the switch position does not agree with the software-set parameters, the printer updates the parameters to the switch settings. Since there is no switch setting for 8-bit data, it will default back to the 7-bit default setting of the switches. This was intended to be a feature.

All changes to the persistent parameters must take place outside the server loop. This is done by exiting the server loop, then sending the necessary changes. The PostScript syntax is listed below.

Caution:

If you choose to use the PostScript code provided in this article, you assume all risks involved in making these changes. PostScript code, if not entered correctly, can place the LaserWriter into a condition requiring service.

```
%=====
% Begin PostScript Code
%
serverdict begin 0 exitserver
statusdict begin
25 9600 3 setsccbatch
end
```

```
%  
% End PostScript Code  
%=====
```

This sets the 25-pin serial interface to 9600 baud with mark parity.

It is possible to have both RS-232 and AppleTalk connected at the same time, but it's necessary to turn off the AppleTalk RS-422 channel before turning on the RS-232 channel. This is done by sending this PostScript code:

```
%=====
% Begin PostScript Code
%
serverdict begin 0 exitserver
statusdict begin
9 0 3 setsccinteractive <-- new line
25 9600 3 setsccbatch
end
%
% End PostScript Code
%=====
```

This turns off the DB-9 (and Mini-8) channel and turns on the DB-25 serial channel for use at 9600 baud. The reverse is possible by changing the appropriate codes.

There are softswitch modes within the LaserWriter IINTX. By using the setsoftwareiomode command, you can specify which software interface will be used to communicate. The options are:

```
0    PostScript Batch
1    PostScript interactive
2    Diablo 630
3,4  Not Used
5    H-P LaserJet Plus emulation
```

In addition to setting setsoftwareiomode, it is necessary to use sethardwareiomode to set the hardware method of communication. The setsoftwareiomode must be done outside the server loop, but the sethardwareiomode can be done within the server loop, which indicates it will not be persistent -- by the old definition of persistent -- but will be in effect only for the duration of the print job.

A complete listing of what we currently believe would perform all the functions with only one code segment might look like this:

```
%=====
% Begin PostScript Code
%
serverdict begin 0 exitserver    % leave server loop
statusdict begin                % push statusdictionary on the stack
9 0 3 setsccinteractive          % turn off RS-422 channel (AppleTalk)
25 9600 3 setsccbatch            % turn on DB-25 serial channel
```

```
setting setsoftwareiomode 5      % Use H-P LaserJet + mode
setting sethardwareiomode 0      % use serial communications
e3,                              % end changes to statusdict
%
% End PostScript Code
%=====
```

If every print job is preceding by this code, or something similar, the parameters should be available when they're needed.

LaserWriter IINT note: The LaserWriter IINT still uses EEROM to store persistent parameters: write life per address of 10,000. The LaserWriter IINTX has a Zero Power RAM with unlimited write cycles to any given address.

LaserWriter IINTX: Switching Modes Using Software, 2 of 2 (2/95)

Revised: 2/23/95
Security: Everyone

LaserWriter IINTX: Switching Modes Using Software, 2 of 2 (2/95)

Article Created: 20 April 1988
Article Reviewed/Updated: 23 February 1995

TOPIC -----

Continuation of how to switch modes using the LaserWriter IINTX.

DISCUSSION -----

You cannot switch FROM an emulation mode on the LaserWriter IINTX using software. It is possible to change TO emulation modes from PostScript mode through software, but you must cycle the DIP switches to get back into PostScript.

If two Macintosh systems, one on AppleTalk and one on a serial connection, are connected to a LaserWriter IINTX, and if the switches are set for LocalTalk (all switches down), you can print from AppleTalk. The following PostScript program changes the printer mode to Diablo 630 and serial communications at 9600 baud:

```
%=====
% Begin PostScript Code
%
serverdict begin 0 exitserver    % exit server loop
statusdict begin                % push statusdict on the stack
9 0 3 setsccbatch               % turn off RS-422 channel
25 9600 3 setsccbatch           % turn on serial channel
2 setsoftwareiomode             % set software mode to Diablo 630
0 sethardwareiomode             % set hardware to serial communications
end                             % end changes to status dictionary
%
% end PostScript Code
%=====
```

This code is similar to that in part 1 of this article, except:

- the syntax on the setsoftwareiomode and sethardwareiomode commands are

corrected

- the sethardwareiomode command is outside the server loop
- secsccinteractive is changed to setsccbatach

This code, if downloaded from an AppleTalked Macintosh, changes the LaserWriter IINTX into Diablo emulation mode and set the serial channel on the DB-25 to 9600 baud. This was verified by sending more PostScript code from the AppleTalked Macintosh, which was ignored. If the printer is power cycled now, the test print will show Diablo mode at 9600, which verifies not only that the printer is in a different mode, but that the persistent parameters do remain after a power off, as they did on a LaserWriter Plus.

Now, a problem: there is a known, but undocumented, problem in the ROMs that does not allow switching the LaserWriter IINTX out of LaserJet mode via software. There is also a problem that does not allow switching out of Diablo emulation mode via software either.

The command sequence is Escape-Delete-0 followed by a Control (Command)-D. This is supposed to interrupt execution of an emulation mode and allow mode changing. When the first part of this code is sent to the printer in an emulation mode, the green light flashes, because the printer sees the code coming in, but the printer will do nothing without the Control (Command)-D. If you then send the Control (Command)-D, the green light stops flashing but the printer is still in emulation mode. This can be verified by sending another file over the serial connection. This problem is being addressed.

In order to get out of any emulation mode with the current version of the ROMs, it is necessary to cycle the DIP switches, to get the printer back into PostScript mode. Power cycling will not accomplish this, but changing the switches will.

To switch modes:

Step 1:

Connect serial device to LaserWriter IINTX via DB-25.

Step 2:

Connect Macintosh via Mini-8 LocalTalk connector.

Step 3:

Set all switches to DOWN position (reversed from manual).

Step 4:

On power-up, test print should show PostScript and AppleTalk on. The printer will now print from the Macintosh.

Step 5:

From Macintosh via a PostScript downloader, send code to switch to serial. The

printer is now accessible from the RS-232 device.

Step 6:

Cycle DIP switches 1 & 2 up, wait 30 seconds, then down again. The printer is now back in PostScript Appletalk mode. If the power is now cycled off and on, the test print will show PostScript and AppleTalk once again.

Here is a code segment that may be of some value when attempting to software switch between modes. Adobe provided this short program that allows going into Diablo emulation mode without actually changing switch settings. This is an internal call to the emulation mode and the mode change persists only for the duration of the print job. Send the following code from PostScript serial mode or PostScript batch mode. Terminate the print job with a Control-D.

CAUTION:

This code could hang the AppleTalk network if both LocalTalk and serial cables/devices are connected at the same time, and this mode is selected via software from the serial (RS-232) connector, and if the AppleTalk channel is not set to the 0-baud rate. This is an undocumented and unsupported feature and neither Adobe nor Apple will be responsible for any problems arising from the use of this code.

System Software: Why All Apple Products Don't Use Same Version

=====

This article last reviewed: 21 April 1988

Various Apple products, even though they leave the factory at the same time, may contain different versions of system software. Here are some reasons why:

- The product may be shipped with the version of system software under which the product was tested. With many Apple products, there is a long test cycle, and it is difficult to re-test the product and change the system software version just before the product's release.
- When new system software is released, it takes time, due to build schedules, for the new software version to be incorporated into the product's packaging.
- Sometimes, a specific modification to the system software is required for a new product. For example, the LaserWriter IISC, which required modifications to the System file and was shipped with System 4.3, which was not a general release.

DiskExpress: It Can Erase Hard Disks to Military Specifications

=====

This article last reviewed: 21 April 1988

If you need software that can erase Macintosh hard disks to military specifications (that is, writes zeros to every location, then ones to every location), a product called DiskExpress may meet your need.

DiskExpress is a disk optimizer for fragmented files and can erase unused blocks. It offers two options to erase unused blocks or the entire volume:

- erase once, writing binary zeros
- erase three times, first writing binary zeros, then binary ones, and finally binary zeros again.

DiskExpress is AppleShare compatible.

For more information, search the Tech Info Library on ALSoft, the publisher of DiskExpress.

A/UX: Changing Kernel Parameters (6/93)

Revised: 8/12/93
Security: Everyone

A/UX: Changing Kernel Parameters (6/93)

Article Created: 14 June 1990
Article Reviewed/Updated: 25 June 1993

TOPIC -----

Where can I find information on kernel parameters? How can I change kernel parameters?

DISCUSSION -----

Beyond minor references in the A/UX documentation suite, there are two places to find information on kernel parameters:

- See the man page for `kconfig(1M)`.
- See `kconfig(1M)` in the "A/UX System Administration's Reference"

Type this command to get a list of current Kernel parameters:

```
kconfig -av /unix
```

The MSGxxx parameters (the ones that deal with messages) and SHMxxx parameters (the ones that deal with shared memory) cannot be viewed or modified via the "kconfig" command, because they are defined and initialized separately inside the kernel. But, by using "adb" (a kernel debugger), you may be able to change these parameters. The last part of this article describes how to change the kernel parameters for the Shared Memory, Messaging Operations, and Semaphores within A/UX 1.0.

The Shared Memory, Semaphore, and Message Operation structures are defined in:

/usr/include/sys/shm.h	Shared Memory
/usr/include/sys/sem.h	Semaphore
/usr/include/sys/msg.h	Message Operations

..TIL02815-A-UX-Changing_Kernel_Parameters_6-93_(TA37949).pdf

The structure members are initialized in /usr/include/sys/space.h.
The values used for initialization are defined in two locations:

```
/usr/include/sys/config.h
../psn/cf/bnetconfig.h
```

The bnetconfig.h file is found only in the source code and is the last file to be read in the build process, so it "overrides" the values in the config.h file. The values listed within this article are those found in bnetconfig.h. In the original version of this article, we verified them by looking at the virgin A/UX 1.0 binary (/newunix).

If you have a version of A/UX prior to Release 3.0.1, you can change parameters with ADB. In A/UX 3.0.1, you can use kconig to set share memory parameters.

Using adb to Change Parameters

Here is how to change the shmseg value from 6 to 12:

```
$ adb -w /unix          # you type the adb command
cannot open core        # system displays
ready                   # system displays
shminfo+c?D             # you type to display the value
                        # in Decimal
shminfo+0xC:            6      # system displays
.?W 0d12                # you type to change the value
                        # in decimal
shminfo+0xC:            0x6 = 0xC # system displays
$q                      # to quit adb, you type
```

To determine the offset and value, look at the tables below, i.e. shmseg is at shminfo+C.

Shared Memory

```
-----
shminfo+0:  262144
    int      shmmax      /* max shared memory segment size */
    #define  SHMMAX      262144

TOPIC -----

What prevents my Macintosh II from overheating if fan fails?

DISCUSSION -----

The Macintosh II power circuit has a safety feature that prevents the system from overheating in the case of a fan failure or blocked ventilation. If the temperature exceeds 65 degrees C (149 degrees F), a thermal switch on the +5V Power Fail Warning current path, through a 220-ohm resistor, opens. The opening of this switch turns off the power supply within 2 ms.

Computer Viruses (part 1 of 4)

Revised: 9/26/94
Security: Everyone

Computer "Viruses" (part 1 of 4)

=====

This article last reviewed: 15 April 1988

GENERAL ISSUES

What is a virus?

A virus is a program with two distinct functions:

- It spreads itself from machine to machine (self-reproducing code). This includes the actual infection of other systems as well as the stashing away of code into as many "carriers" as possible.
- It implements the "symptoms" planned by the perpetrator of the virus. This could be any number of things, up to and including erasing a disk on a specific date.

A Bit of History

Computer viruses have been around for almost as long as computers. John Van Neumann, the father of the modern computer, toyed with the idea of self-reproducing computer code as early as 1948. In the late 1970s, there was even a training ground for the writing of viruses. It was a program called Core Wars that implemented an artificial environment pitting two virus programs against each other.

Viruses Are Not Unique to the Macintosh

The Macintosh is not the only system to be plagued by viruses. Mainframe and minicomputers are also targets for virus programmers. One of the more recent mainframe incidents was the virus that invaded IBM's mail system and brought it to its knees for a couple of days. IBM PC users have been experiencing viruses for several years now. The most common method of attack is through the COMMAND.COM file. The Macintosh community has been lucky to have gone so long without virus programming becoming the thing to do.

Not All Viruses Are Meant To Be Damaging, But...

Viruses are not all meant to be damaging. The programmer may just want to prove he can do it and have the satisfaction of reading about it in magazines and on the BBS network. Sometimes, these viruses can cause problems anyway. For example, the virus that has prompted this series of articles was meant to be benign except in specific cases. However, it takes up memory and processing time and has caused random side effects such as printing problems and system crashes.

Don't Panic; Don't Overreact

If you think that you have a virus, it's important to not overreact. It is important to take a step back and evaluate the situation calmly. Once you know that you have a virus and what it has infected, it is a relatively easy thing to combat. This document contains enough information for you to deal with most viruses.

Unix Viruses

In all of this, there has not been much discussion of Unix viruses, but they do exist, and the spread of public domain software is almost as great in the Unix world as it is in the microcomputer world.

THE GREAT VIRUS HUNT

When Do You Suspect You Might Have a Virus?

When your computer begins to do things out of the ordinary, or when it stops being able to do things it has always done in the past. The problem with this is that corrupted system files can lead to similar symptoms even though a virus isn't involved. When problems occur, they are much more likely to be the result of non-virus difficulties. When you have ruled out the standard problem areas, you should look into the possibility that your system has been infected by a virus.

What to Look For If You Think You Have a Virus

Look for invisible files in your System folder that don't belong there. Unless you specifically have an application that creates invisible files in the System folder, every invisible file in the System folder should be suspect. Also, a general check of all the files in your System folder for resources that don't belong in those files is well worth the effort.

Files and Resources a Virus Might Infect

- Any and all applications
- HyperCard Stacks (the MacMag virus was spread via a HyperCard stack)
- Files in the System folder, including:

System
Finder
Note Pad file
Scrapbook file
Clipboard file
Easy Access
Sound
Mouse
Startup Device
Monitors
Color
General
Keyboard
LaserWriter
ImageWriter
AppleTalk ImageWriter
ImageWriter LQ

In other words, all system files.

Files a Virus Might Damage Inadvertently

- Any file on an infected volume or system, including system files, documents, applications, etc.

Public Domain Issues

Most viruses spread via public bulletin board systems and are hidden in public domain programs. "Sexy Ladies," a program distributed at a MacWorld Expo in San Francisco, erased whatever hard disk or floppy disk it was on when it was launched.

Network Issues

The use of networks can easily enhance the spread of a virus. Different scenarios are possible, with the simplest being a public domain folder on a server that everyone gets the latest neat stuff from. Also, shared applications residing on a server could become infected, which would then infect every machine that those applications were run on.

TECHNICAL ISSUES

How Viruses Propagate

Viruses can propagate by a variety of methods. The most common way for a Macintosh virus to replicate itself is to have an INIT that installs a background (VBL) task that checks for specific occurrences, such as a disk insertion, and then copies itself somewhere to that disk.

VBL Tasks

The Macintosh has always had a limited form of background processing available to it through the use of the Vertical BLanking queue. Every time the screen on a Macintosh (except for a Macintosh II) is refreshed, any routines installed in the queue are executed. The Macintosh II has a dummy VBL queue for compatibility reasons since the advent of a variety of screens has led to different vertical retrace periods.

VBL tasks can be installed in the queue by any program. The program has to load a routine into a section of memory and install the routine into the VBL queue by calling the Vinstall ROM routine. It is the responsibility of the installing program to make sure the segment of memory containing the routine remains available even after the program has exited. Each VBL task has a specified time period it should be left "asleep" before it is called. Every time the routine is executed, a counter is decremented for that routine. When that counter reaches zero, the routine is deleted from the queue unless the routine itself resets the counter.

Lengthy VBL tasks such as the one that might be used to replicate a virus can interfere with the normal operation of the Macintosh by interrupting processes that shouldn't be interrupted. A perfect example of this is printing to a LaserWriter over an AppleTalk network. If a VBL task takes too long in its execution, the printing process could terminate abnormally

and leave the machine's connection to the network in an unstable state.

For the purposes of a virus, an INIT is most likely to be the culprit responsible for installing a VBL task.

INITs

INITs are routines that are run when the Macintosh is booted. For the most part, they have full access to all of the commands normally available to a standard Macintosh program. The major difference is that the low memory globals have not been set up yet, so any INIT needing access to structures normally stored in low memory must create its own.

INITs in the System file:

When a Macintosh boots, the INITs in the System file in the "blessed" folder are the first code to be executed. These INITs should generally be Apple INITs only -- any non-Apple INITs should be considered suspect.

The INIT 31 mechanism:

A special INIT in the System file, INIT 31, was created to allow for the execution of non-Apple INITs without having them installed in the System file itself. When all of the other INITs in the System file have been executed, INIT 31 walks through the System folder looking for files of types INIT, RDEV, cdev, and executes any INIT resources it finds in these files. The order in which the files get loaded is alphabetical. Needless to say, a simple way for hiding parts of a virus is to drop INITs into legitimate files already existing in the System folder with these file types.

CDEVs

The file type cdev indicates a file containing a Control Panel device. When the Control Panel is loaded, it walks through the directory of the System folder looking for any files of type 'cdev'. When it finds a file of this type, it loads the ICN# of that file (assuming it has one) into the list of icons shown on the left side of the Control Panel. When you click on the icon of the cdev in the Control Panel, the code in the cdev resource in the file of type 'cdev' is executed. A virus could easily use this mechanism as a way to infect a system, install a VBL task, etc.

Many cdev files have INITs in them with the cdev controlling the settings that the INIT will use when it is installed. A good example of this is the settings for a screen blanker. The INIT actually installs the VBL task, but the cdev controls when dimming occurs. None of the standard Apple system cdev files have INITs in them, but there is nothing to prevent a virus installing an INIT in these files as a way of hiding its code.

DRVRs

DRVR resources typically can have one of two functions: they can be the code for a desk accessory, or the code for drivers necessary for the system to perform some function such as printing. Once again, the key word here

is 'code'. Whenever code is involved, the potential arises for the perpetrator of a virus to take advantage of it.

Just as with cdevs, when a DRVr gets opened, either by the choosing of a desk accessory or by the system, code is executed at that point. This is the stage at which a virus might fulfill its purpose.

CODE Resources

Each application has at least two CODE resources. The first of these CODE resources has an id of 0 and contains what is known as the jump table. This table provides the basic information necessary for various parts of a program to call routines in other CODE segments. The current rage in viruses is to modify the CODE ID = 0 resource of an application so that a CODE segment it installs in the application gets called before the application is actually run. This CODE segment could go out and check if the virus has infected the current system, and if it hasn't, install itself. All the perpetrator of a virus has to do at this point is upload a copy of an infected application to a BBS, and it spreads across the world.

Applications that allow external procedures:

Viruses could take advantage of the external procedures that are allowed by some applications. The perfect example of this is HyperCard, with its XCMDs and XFCNs. This is how the MacMag virus was transmitted.

KNOWN VIRUSES

The Scores Virus

You can be almost positive your system has been infected by the Scores virus if the icons of your Note Pad file and Scrapbook file look like document icons instead of system icons. Launch ResEdit and look in your System folder. If you see files called "Desktop" and "Scores" you can be 99% sure that you have the Scores virus.

How Scores Spreads and What It Does

The Scores virus is relatively harmless. The initial infection is caused by an application with a modified CODE ID = 0 resource, and an additional CODE resource (first unused ID number plus 1). When the 'carrier' application is launched, the CODE ID = 0 resource runs the virus installer code. This code checks for previous installation of the Scores virus. If the virus is not there, the virus files are installed. The virus consists of three INITs, one atpl, and one DATA resource found in the files listed below:

FILE	TYPE	CREATOR	RESOURCES		SIZE

Desktop (invisible)	INIT	FNDR	atpl	ID = 128	2410 bytes
			DATA	ID = -4001	7026 bytes
			INIT	ID = 10	1020 bytes
Note Pad File	INIT	ZSYS	INIT	ID = 6	772 bytes
Scores (invisible)	RDEV	ZSYS	atpl	ID = 128	2410 bytes
			DATA	ID = -4001	7026 bytes
			INIT	ID = 10	1020 bytes

Scrapbook File	RDEV	ZSYS	INIT	ID = 6	772 bytes
				ID = 17	480 bytes
System File	ZSYS	MACS	atpl	ID = 128	2410 bytes
			DATA	ID = -4001	7026 bytes
			INIT	ID = 6	772 bytes
			INIT	ID = 10	1020 bytes
			INIT	ID = 17	480 bytes

If the Note Pad and Scrapbook files do not exist, they are created. If they exist, the type and creator of the files are altered to those listed above, and the corresponding resources are added to the files. The files still appear to function normally with the Note Pad and Scrapbook DAs, but their icons change to document icons. The Desktop and Scores files are invisible, and are created during the infection process.

The next time the infected system is rebooted, the INITs are loaded into memory and are ready to infect other applications. The INITs install a VBL task that actually modifies and installs resources into an application. After an application has been launched, an internal timer is started. Somewhere between two and three minutes later, the open application is infected and becomes a carrier. A new CODE resource is added to the infected application, and the application's CODE ID = 0 resource is modified to execute the new CODE resource first, then continues with the application.

To determine if an application is infected, examine the CODE ID = 0 resource. If the eleventh word of the resource (third word on the third line in the ResEdit listing) is NOT "0001", the application is suspect. If the third word is something other than "0001", convert the value to its decimal equivalent (the numbers are in hexadecimal). Then determine the resource number of the CODE resource at the top of the ResEdit resource list. If these numbers are the same, the application is probably infected, and should be replaced. Some applications will appear to be infected even though they are not. If the eleventh word of CODE ID = 0 is not 1, check the tenth word; if it is '4EED' the application is most likely not infected.

How to Get Rid of the Scores Virus

It is not hard to remove this virus from a system, but it may take some time. Here's how:

1. Use Font/DA Mover to copy all fonts and DAs that you do not have backups of to font and DA suitcase files (this virus does not attach itself to DAs).
2. Start the system from a locked, not infected, floppy disk.
3. Throw away the System folder on the infected disk.
4. Use ResEdit to identify all suspect applications on the infected disk.
5. Make a list of all suspect applications.

6. Throw all suspect applications in the trash, and empty the trash.
7. Reinstall the system software from a known good System Tools installer disk.
8. Using locked masters, recopy any applications that were deleted from the infected disk (it is important to verify that the master disks have not been infected).
9. You're all done.

The nVIR Virus

How the nVIR Virus Spreads and What It Does

The nVIR virus is similar to the Scores virus in many ways. It does not appear to have malicious intent and is relatively harmless. Initial infection of a system is also caused by an application with a modified CODE ID = 0 resource. When a nVir carrier application is launched, the virus' code segment is executed first. This code checks for its INIT in the System File, and if it doesn't find it, the code copies the INIT there. Along with the INIT resource, eight 'nVIR' resources (0-7) are added to the System file.

The next time the system is restarted, the INIT ID = 32 is loaded into memory and tries to infect every application that is launched. The nVir virus adds a CODE ID = 256 resource and modifies the CODE ID = 0 so that the nVir code is executed first.

Again, infection of an application is determined by examination of the CODE ID = 0 resource. If the eleventh word of the resource (third word on the third line in the ResEdit listing) is NOT "0001", the application is suspect. If the third word is something other than "0001", convert the value to its decimal equivalent (the numbers are in hexadecimal). Then determine the resource number of the CODE resource at the top of the ResEdit resource list. If these numbers are the same, the application is probably infected, and should be replaced. Some applications will appear to be infected even though they are not. If the eleventh word of CODE ID = 0 is not 1, check the tenth word; if it is '4EED' the application is most likely not infected. The tenth word normally contains '3F3C'.

When launching an infected application, there is a one in sixteen chance that you will hear a short system beep. We have been told that if MacinTalk is installed you will hear the words "don't panic".

How to Get Rid of the nVIR Virus

Remove the nVIR virus the same way you remove the Scores virus except you do not need to throw away all of the files in the System Folder; just throw away the System file.

The MacMag Virus

We don't have much information regarding the MacMag virus. It was apparently uploaded to CompuServe, inside a HyperCard stack, in the form of an XCMD, and it installed an INIT ID = 6 with a name of 'RR'. Its sole purpose in life was to display a "universal message of peace" on your computer on March 2, 1988. The virus removed itself after displaying this message and should be of little concern now.

SAFEGUARDING YOUR SYSTEMS

What Makes Our System Susceptible to Viruses

The various mechanisms described in part 2 of this article make our system easy to infiltrate by a virus. Remember that it is those same mechanisms that add to the flexibility and "look and feel" of the Macintosh. For instance, the INIT mechanism is used by mail systems to load their code in. AppleShare uses the INIT mechanism to mount network volumes at boot time.

Why Vaccine Works in This Case, But Is Easy to Bypass

Vaccine, a public domain INIT written to block viruses, does a good job of alerting you when the three known viruses are trying to infect your system. The problem with Vaccine: once a cure is found for one set of viruses, a new strain may appear that knows how to bypass the existing defenses.

Some Suggestions

- Lock your master diskettes

Always keep original "Master" disks locked. This prevents a virus from spreading to your original disks. Our disk locking mechanism is hardware based -- viruses can't infect locked disks!

- Protect your networks

Network administrators should not allow just anyone to put software on the server. Applications on a network server should come only from known good masters.

- Be wary of public domain software

Public domain software should be checked quite thoroughly on a floppy-based system for any infections before being copied to a hard disk based system. This will also protect you from any "Trojan Horse" programs such as "Sexy Ladies."

- Quarantine infected systems

If you identify a system as being infected with a virus, immediately isolate (quarantine) it from other systems. This means disconnecting it from any network and not allowing anyone to take any files from the exposed system to another system. Once the system has been 'disinfected,' you can allow the files to be copied or moved.

- Use ResEdit

ResEdit is a good tool to look for viruses on your disks. There is very little that can be hidden from ResEdit, so you can use it to remove troublemaking files and resources.

HyperCard 2.x, HyperCard Player: Error Code List (12/93)

Revised: 12/13/93
Security: Everyone

HyperCard 2.x, HyperCard Player: Error Code List (12/93)

=====

Article Created: 13 December 1993

TOPIC -----

What error information does HyperCard 2.x and the HyperCard Player report?

DISCUSSION -----

Both HyperCard 2.x and the HyperCard Player use a similar format for reporting errors. While HyperCard 2.x delivers an error number and explanation, the HyperCard Player simply reports the error number.

HyperCard Player Error Message Details

HyperCard Player Error Messages are reported in the following format:

"Error number <errorNumber> occurred"

In this format, errorNumber is a string consisting of two parts:

- (1) The letter code indicating which error string list to refer to.
- (2) The string number within that resource to refer to. The letter codes for the string resources are:

Letter -- String Resource
e -- Error Strings
t -- Talk Errors
s -- Script Strings
d -- Dialog Strings

For example, an error message might state:

"Error number t100 occurred"

In this example, the "t" refers to the string resource "Talk Errors" and "100" is string number 100 within that resource ("Handler Too Long").

Another example might state:

"Failed to Compact Stack. Error number e55 occurred."

In this example, HyperCard couldn't compact a stack, because some resources were still in use. The "e" refers to string resource "Error Strings" and "55" refers to string number 55 ("Resources are in use").

For a complete listing of Error Strings, Script Strings, HyperTalk Errors and Dialog Strings, see the appropriate portion of this article.

(Errors marked with asterisks (*) are not included in the HyperCard Player)

Error Strings - string #140

- 1--This version of HyperCard requires System 6.0.5 or later.
- 2--HyperCard does not have enough memory to continue.
- 3--That tool is not available at the current user level.
- 4*--Couldn't edit script of that object.
- 5*--Can't open script editor.
- 6*--Can't open Message Watcher window.
- 7*--Can't open Variable Watcher window.
- 8*--Failed to open icon editor. Couldn't read resource file.
- 9*--Can't use that ID. The ID must be a number in the range 128 to 32767.
- 10--Passwords don't match.
- 11--Can't save changes to text.
- 12--Can't save changes to picture.
- 13--Nothing to copy. Try background.
- 14--Can't modify this stack.
- 15--This stack is read only.
- 16--This stack has not been converted. It must be converted before it can be modified.
- 17--Failed to copy picture.
- 18--Failed to create new card.
- 19--Failed to copy card.
- 20--Failed to paste card.
- 21--The clipboard is too big to paste.
- 22--Picture too big to cut or copy. Try copying in sections.
- 23--Can't delete last card. Use delete stack instead.
- 24--Can't delete protected card.
- 25--Can't delete last card of protected background.
- 26*--Can't find the Home stack.
- 27--Can't open stack "^0".
- 28--Not enough memory to ^0.
- 29--import paint
- 30--export paint
- 31--delete stack
- 32--rename stack
- 33--copy stack
- 34--create stack
- 35--compact stack
- 36*--edit icon

37*--continue debugging
38--complete that command
39--use the painting tools
40--show the recent cards
41--display the card picture
42--display the background picture
43--copy the selection to the Clipboard
44--Failed to ^0. ^1
45--Can't open stack "^0". ^1
46--File system error ^2.
47--Disk is full.
48--Too many files open.
49--File is busy.
50--File is locked.
51--File access denied.
52--Existing file is not a HyperCard stack.
53--Existing file is not a MacPaint document.
54--Can't replace an existing file.
55*--Resources are in use.
56--Stack may be corrupted.
57--Stack is protected.
58*--It is the current Home stack.
59--Colon not allowed in name.
60--Return not allowed in name.
61--Bad data in MacPaint file.
62--File system error ^0 while ^1 the disk.
63--reading from
64--writing to
65--New file format requires new version of HyperCard.
66--Old file format.
67--The file is not a HyperCard stack.
68--Can't type more than 30,000 characters into a field.
69--Not enough memory to display the text for this field. Try compacting
the stack.
70--HyperCard needs more memory to run at this color setting. Please set
the monitor back to Black & White.
71--HyperCard needs more memory to run at this color setting.
72--No more windows can be opened.
73--The first character of a stack name can't be a period.
74--Can't edit scripts while debugging.
75*--Can't choose from HyperCard's menus here.
76*--You can choose only from the Debugger menu while debugging.
77
78--Can't replace an existing file that's of a different type.
79--replace

Script Strings - string #135

1*--on mouseUp
end mouseUp
2*--Not enough memory to print.
3*--Selection too large.
4*--Not enough memory to open script editor.

5*--Can't modify this script.
6*--Not enough memory to format script.
7*--Failed to save script.
8*--Got error ^0 when trying to open script editor.
9*--Can't set more than 16 checkpoints in a script.
10*--Set Checkpoint
11*--Clear Checkpoint
12*--Clear All Checkpoints
13*--Print Script
14*--Print Selection
15*--Close Script
16*--Close All Scripts
17*--
18*--Not enough memory to use the Message Watcher.
19*--Not enough memory to use the Variable Watcher.
20*--Not enough memory to use Script Editor.
21--Oh yeah?
22*--The changes to your script will not be saved because the stack can't be
modified (unlock the stack if you want to save the changes).
23*--Not enough memory to edit that variable.
24*--Save changes to ^0?
25*--Failed to revert changes.
26*--Do you really want to discard changes to ^0?
27*--Hide unused messages
28*--Hide idle
29*--This script has been changed since it was last saved. Do you wish to
continue?
30--button
31--Display what picture?
32--

Talk Errors - string #132

1*--No such stack.
2*--No such card.
3*--Can't access fields or buttons in other stacks. Use "go".
4*--Can't DIV by zero.
5*--Can't MOD by zero.
6*--Destination does not contain a number.
7*--No open file named "^0".
8*--Can't find menu item "^0".
9*--Translator failed to translate the message box into English.
10*--Can't find "^0".
11*--Can't open any more files.
12*--Can't close that window.
13*--Got error ^0 while trying to open file "^1".
14*--There is no ^0 ^1 number ^2.
15*--Not enough memory to read from file.
16*--Got file system error ^0.
17*--No such button or field.
18*--Can't set that ^0 property.
19*--There is no ^0 ^1 id ^2.
20--button

21--field
22--card
23--bkgnd
24--stack
25--HyperCard
26--window
27*--Not a scrolling field.
28*--Can't set properties of that object.
29*--Sort by what?
30*--Not enough memory to sort this stack.
31*--Error writing to file "^0".
32*--Translator failed to indent.
33*--Fields can't hold more than 30000 characters.
34*--Couldn't set that field.
35*--Couldn't load external command.
36*--Too much recursion.
37--Out of memory.
38--HyperCard Help
39*--Can't find icon named "^0".
40*--Script of
41*--Expected ")" but found "^0".
42*--Expected ")".
43*--Too many nested repeats.
44*--Can't understand that message.
45*--Only fields, buttons, cards, and backgrounds have numbers.
46*--Can't take the value of that expression.
47*--Can't get that property.
48--Can't understand arguments of "^0".
49*--Found "exit repeat" outside a repeat loop.
50*--Already have a local variable named ^0.
51*--Too many pending messages.
52*--"^0" is not an application.
53*--There is no ^0 ^1 named "^2".
54*--There isn't any selection.
55*--Too many nested blocks.
56*--end of line
57*--Found "next repeat" outside a repeat loop.
58*--Translator failed to translate indent strings.
59*--Translator failed to initialize itself.
60*--Can't load that translator.
61*--Can't find a translator for that language.
62*--Old translator failed on quit.
63*--Can't understand "^0".
64--Script too silly to execute.
65*--Failed to sort this stack.
66*--User level is too low to edit scripts.
67*--Can't edit script of HyperCard.
68*--Couldn't edit script of that object.
69*--Only cards and backgrounds have pictures.
70*--^0 was not a valid expression for any card.
71*--Can't have more than 16 parameters for an external command.
72*--Only start and stop using can change the stacksInUse.
73*--Can't modify that menu.

74*--That ^0 name is too long.
75*--File "^0" is already open.
76*--Too many types.
77*--Too many responses.
78*--No such bkgnd.
79*--Can't create that file.
80*--The sort key
81*--Stack not in use.
82*--Expected "of" after this function.
83*--Can't understand arguments to this function.
84*--Can't understand arguments to this keyword.
85*--Can have "else" only after "then".
86*--Can't have "end" here.
87*--Too many "exit repeats".
88*--Expected "end if" after "then".
89*--Expected end of line after "end if".
90*--Can't duplicate stack.
91*--Expected "end if" after "if".
92*--Expected "end if" after "else".
93*--"On" can appear only once per handler.
94*--Expected "end" after "on".
95*--Expected "end ^0"
96*--Extra statements after end of handler.
97*-- Expected "end repeat" after "repeat".
98* --Expected end of line after "end repeat".
99*-- Can have "then" only after "if".
100*--Handler too long.
101*--Can't get scroll of that window.
102*--Expected a variable name but found ^0
103*--Can't set scroll of that window.
104*--Can't set rectangle of that window.
105*--Can't set that property.
106*--String too long.
107*--No such menu item.
108*--Menus don't have that property.
109*--menu
110*--No such menu.
111*--Too many menus with messages.
112*--That button or field has been deleted.
113*--Expected ^0 here.
114*--Expected stack here.
115*--Already have a menu named ^0.
116*--Expected a field here but found a button.
117*--Expected a button or field here.
118*--Expected a point but found ^0.
119*--Expected a rectangle but found ^0.
120*--No such card or bkgnd.
121*--Can't start using that stack.
122*--Can't start using home.
123*--Too many stacks in use.
124*--The translator failed to translate that script into English.
125*--Not handled by target program.
126*--Expected "true" or "false" here but found ^0.

127*--Number of menu messages must be equal to number of menu items.
128*--Couldn't send to that window.
129*--Don't know how to tell if something is a ^0.
130*--Can't open the Message Watcher named ^0.
131*--Can't open the Variable Watcher named ^0.
132*--Can't load that external.
133*--Expression too complicated.
134*--Can't open stack
135*--Can't open stack's resource fork.
136*--Couldn't open that application.
137*--Couldn't import paint.
138*--Couldn't export paint.
139*--Invalid date.
140*--Invalid expression.
141*--Couldn't create stack.
142*--Can't find that icon.
143*--No such window.
144*--number
145*--integer
146*--true or false
147*--Can't understand this.
148*--No current Apple® event.
149*--Too many windows open.
150*--Can't modify this stack.
151*--Not supported by this version of the system.
152*--No such program.
153*--Expected a number between 1 and 255 here.
154*--Expected a single character here.
155
156--An error occurred (^0).
157--Script error (^0).

Dialog Strings - string #129

1*--^0 out of ^1
2*--Card
3*--Bkgnd
4--Where is ^0?
5--What's the password?
6--New stack name:
7--Save a copy of stack as:
8--Copy of ^0
9--Save Paint document as:

LaserWriter IINT/NTX: Two Corrections to Owner's Guide

=====

This article last reviewed: 19 April 1988

The "LaserWriter IINT/NTX Owner's Guide" (030-315-A), in the section titled "Using the 25-pin connector," fails to mention that a modem eliminator is needed. The complete connection is:

25-pin serial cable
to
25-pin Apple Modem Eliminator (590-0166-A)
to
serial port on LaserWriter II

In the subsection "Making the connection," step 6, the MS-DOS commands should be:

```
MODE COM1:96,N,8,1,P  
MODE LPT1:=COM1:
```

With the commands in the manual, Shift-* doesn't print the screen as it's supposed to.

LaserWriter IINTX: Printing in H-P LaserJet+ Mode

Revised: 9/22/89
Security: Everyone

LaserWriter IINTX: Printing in H-P LaserJet+ Mode

=====

This article last reviewed: 19 April 1988

H-P LaserJet+ Emulation mode is a command emulation mode: most of the H-P LaserJet+ commands are accepted by the LaserWriter IINTX. This does NOT mean that the output will always duplicate exactly the output from an H-P LaserJet+.

While a command may be accepted, the output will be calculated and performed by the same line-drawing routines and functions used when PostScript commands are printed. The LaserWriter IINTX is not optimized for the H-P LaserJet graphics commands.

This difference may cause problems with MS-DOS programs that require H-P LaserJet+ graphics precision. For example, with a bar-code printing program, the lines may not meet the exact tolerances (width or size) of the H-P LaserJet+.

In H-P LaserJet+ emulation mode, the LaserWriter IINTX is not as fast as in PostScript mode, because graphics must be interpreted by PostScript. In addition, in H-P LaserJet+ emulation mode, the LaserWriter IINTX is not as fast as the H-P LaserJet+ itself.

PostScript LaserWriter and Font RAM Availability (3/94)

Revised: 3/31/94
Security: Everyone

PostScript LaserWriter and Font RAM Availability (3/94)

=====

Article Created: 16 March 1988
Article Reviewed/Updated: 2 September 1993

TOPIC -----

This article describes PostScript LaserWriter font RAM availability.

DISCUSSION -----

The available RAM for downloadable fonts on PostScript LaserWriters is dynamic, and is affected by several factors. Two of these are paper size and downloaded PostScript programs (for example, the ImageWriter Emulator used by Apple II users). Note that downloadable fonts use RAM that may be needed by a complex print job. Loading up the RAM with too many may result in limitcheck or other memory errors when printing.

The following PostScript program will print a page with the available Virtual Memory (VM):

```
/Helvetica findfont 12 scalefont setfont
72 720 moveto
(Available VM: ) show
vmstatus exch sub 10 string cvs show
showpage
```

If the number returned is greater than the number of bytes in the font file, there should be enough room to download the font.

The available RAM for fonts also changes depending on paper size. The larger the paper, the less RAM available for downloadable fonts.

If you have built-in typefaces, there is no limit to the number of different fonts used on a single page. The available RAM in the LaserWriter will limit the variety of downloadable typefaces.

On the LaserWriter IISC, Personal LaserWriter SC, Personal LaserWriter LS,

Personal LaserWriter 300 and LaserWriter Select 300, the only limit on the number of different fonts on a single sheet will be the number of fonts available via the font selection process of a particular application.

Article Change History

Enhanced Apple IIe: MouseText Problem Solved By AppleWorks V2.0

=====

This article last reviewed: 30 March 1988

Some users have asked about a version of AppleWriter for the enhanced Apple IIe, since there are conflicts with the enhanced Apple IIe's MouseText function (you can tell if the computer is enhanced if it displays "Apple //e" rather than "Apple][" on the screen at startup).

AppleWriter 2.0, ProDOS version, resolved this problem for the enhanced Apple IIe, but is no longer on the price list.

If you don't have this version, you may use an alternate word processing program. One such program that does not conflict with MouseText is AppleWorks 2.0.

AppleShare 2.0: Questions About New Features

=====

This article last reviewed: 30 March 1988

Here are three questions (and answers) about AppleShare 2.0:

Q. Is AppleShare File Server 2.0 only a server software upgrade, or is the workstation software upgraded as well?

A. AppleShare File Server 2.0 comes with updated workstation software (version 2.0).

Q. Does version 1.1 workstation software work properly with 2.0 server software?

A. Version 1.1 workstation software can access the Appleshare File Server 2.0, but does NOT access the new features that version 2.0 workstation software provides.

Q. Are you still limited to one group at a time while accessing privileges?

A. Only one group at a time can be accessed while accessing privileges.

How to Prevent Changes to Application Names

Revised: 5/17/89
Security: Everyone

How to Prevent Changes to Application Names

=====

Article Created: 5 April 1988
Article Last Reviewed: 14 July 1992
Article Last Updated: 14 July 1992

You can prevent someone from changing a file name (such as the name of an application), without having to lock it. You can use the same method that makes the System file's name unchangeable.

The System file's name cannot be changed because the "System" bit in its Finder information section has been set.

You can set the "System" bit of ANY application using ResEdit (for this example ResEdit 2.1.1 was used):

1. Run ResEdit.
2. Select "File/Folder Info..." from the File menu.
3. Find the application and open it.
4. Find the checkbox to the right of the application name on the top line.
6. Click once in the box.
7. Click in the Close box of the window.
8. Click on the "Yes" button to save the settings.
9. Repeat steps 2 through 8 until all the applications are changed.

(NOTE: If a file with the "System" bit set is duplicated using the Duplicate command in the Finder's File menu, the new file will not have the "System" bit set.)

A/UX: Printing And Shared Spooling Without AppleTalk (8/95)

Revised: 8/23/95
Security: Everyone

A/UX: Printing And Shared Spooling Without AppleTalk (8/95)

=====

Article Created: 14 February 1989
Article Reviewed/Updated: 23 August 1995

TOPIC -----

You can serially connect any of the following printers to any Macintosh on the network and set up an A/UX spooler on that system even without AppleTalk and LaserShare:

- LaserWriter
- LaserWriter Plus
- LaserWriter IINT
- LaserWriter IINTX
- ImageWriter
- ImageWriter II
- ImageWriter LQ

Other A/UX Macintosh computers will then have access to the printer via remote commands.

DISCUSSION -----

Making the Connection

1. Connect an Apple IIe Modem-8 cable to the DB-25 port on the printer. The ImageWriter II and ImageWriter LQ require an Apple System/Peripheral 8 Cable. (Search the Technical Info DataBase on "A/UX and printer and cable" for more information on the various cables you can use.)
2. Connect the mini-circular 8 end to the printer port on the Macintosh (tty1) only.
3. Adjust LaserWriters to Serial Settings (ImageWriter LQ may also need to be reset from default):

a. LaserWriter and LaserWriter Plus:

When hooking up serially, the switch in the back of the LaserWriter or LaserWriter Plus MUST be turned to 9600 baud (as opposed to AppleBus). Without special serial drivers that can communicate PostScript, files cannot be printed from within the Macintosh Operating System without switching the Baud to AppleBus and the cable to AppleTalk.

(For additional information, see the A/UX Local System Administration manual chapter on "Managing Printers, Terminals and Modems".)

b. LaserWriter IINTX:

Set the dip switches on the back to:

1, 2 down (1:up and 2:down will also work)

4-6 up

On powerup, the test page should indicate Postscript at 9600 Baud

NOTE: On some NTX prototypes, the settings should be reversed: down instead of up. Reverse the switch directions if the test page reflects a difference. (For additional information, consult the LaserWriter II Owner's Guide.)

c. LaserWriter IINT:

Set the dip switches on the back to:

1 up

2 down

On powerup, the test page should indicate Postscript at RS-232 9600 Baud.

NOTE: On some NT prototypes, the settings are reversed; that is, down instead of up. Reverse the switch directions if the test page reflects a difference (for additional information, consult the LaserWriter II Owner's Guide).

d. ImageWriter LQ:

A/UX software additions must be made if you wish to use the 19200 Baud instead of 9600 Baud. (See Spooling below for 19.2K setup instructions) For 9600 Baud the dip switches are: set 2: 1,2 closed for 9600.

Spooling

The complicated and time-consuming chore of setting up a spooler is reduced to an invaluable shell script that will automatically set up the entire spooling system by simply naming the printer and the port to which it is attached.

"ADD_IW ImageWriter tty1" will set up an ImageWriter I or II (or 9600 Baud ImageWriter LQ, see *** below) spooler with the name "ImageWriter"

"ADD_LW LaserWriter tty1" will set up any LaserWriter spooler with the name "LaserWriter"

"RM_PR printername" will remove that spooler.

NOTE: If you have jobs in the queue destined for that printer, you will not be able to remove it until you remove the jobs ("cancel request_id(s)"). This will happen if you disconnect the printer while it still has jobs it hasn't printed yet, or is unable to print.

NOTE: A/UX Release 1.0 does not contain lp interface software for 19200 Baud printers. If you want to use the LQ at 19200 Baud follow the directions below:

1. Copy the ImageWriter model (located in "/usr/spool/lp/model") to iw19.2
2. Edit by adding 19200 to the "stty" command.
3. Save it.
4. Copy the file "/usr/spool/lp/ADD_IW19.2" to "/usr/spool/lp/ADD_IW19.2"
5. Substitute ImageWriter for iw19.2 in the /usr/spool/lp/ADD_IW19.2 by
":1,\$s/ImageWriter/iw19.2/".

You will now have a 19.2 interface. When you wish to use the LQ at 19200 Baud issue the command, "lp -diw19.2 filename"

If the dip switches are set to 9600 Baud issue the command, "lp -diw filename" (If ImageWriter is your default, the -d option is unnecessary)

Remote Printing

If you are on an Ethernet system, issue the command:

```
"cat myfile | remsh PrinterNodeName lp printername"
```

where:

- "myfile" is the file you wish to print.
- "PrinterNodeName" is the hostname of the A/UX system that has the printer attached.
- "printername" is the name you have assigned to the printer (such as LaserWriter with the ADD_LaserWriter command).

Macintosh II: MacFortran Error When Making New Palette Calls

Revised: 5/3/88
Security: Everyone

Macintosh II: MacFortran Error When Making "New Palette" Calls

=====

This article last reviewed: 5 April 1988

Some users have experienced a problem using Absoft's MacFortran on the Macintosh II:

The software includes a sample Fortran routine for addressing the palette manager (Call to New Palette). When running the routine on a Macintosh II WITHOUT expanded video memory, the routine will return a proper handle.

However, when run on a Macintosh II with expanded video memory, a null handle may be returned (even when set for 16 colors). Addressing the resource file with Get New Palette has the same results.

One possible solution is increasing the application stack size. If you have a default of 24K, it may be too small for creating your own palette to handle the additional colors. An example program demonstrating how to increase the application stack size is shipped with MacFortran.

Also, if you are running your program under MultiFinder, try increasing the program size (Select Program, then choose Get Info from File menu). The default setting is approximately 385K; you might increase this to 512K or more (depending on your program requirements, and how much RAM you have in your system).

Macintosh II Video Cable: Length Affects Performance

Revised: 7/2/92
Security: Everyone

Macintosh II Video Cable: Length Affects Performance

=====

Article Created: 29 March 1988
Article Last Reviewed: 30 June 1992
Article Last Updated:

TOPIC -----

What is the maximum length of Video Cable that can be used with the Apple High Resolution Monitors?

DISCUSSION -----

Apple formally supports only the monitor cables and cable lengths available through Apple--but theoretically, using 75 ohm impedance value cable (usually RG59U standard coaxial video cable), the signal will be very reliable up to 50 feet.

The distance is limited by the loss of signal strength through cable resistance:

- Specifications: 75 ohm impedance cable
- Signal strength: 13.33 amps; 1 volt
- Signal in MHz: 30.24

The DB loss per foot (or attenuation) using an RG59U standard cable is approximately .0015--resulting in a power loss of 4% of the original 1 volt signal at 100 feet.

The signal will drop to 50% at 2000 feet, with a 3 DB drop in power. Apple recommends staying within 95% percent of the signal, which would be under 150 feet. Increasing the monitor brightness control can correct for some of the signal loss.

(NOTE: Because of the TTL sync signal for the Apple High Resolution Monitors, it is unlikely the monitor will work correctly with sync signals under 4 volts, which would be a cable about 650 feet in length.)

AppleShare and AppleShare PC: How Much RAM Does It Use?

Revised: 8/25/89
Security: Everyone

AppleShare and AppleShare PC: How Much RAM Does It Use?

=====

This article last reviewed: August 23 1989

Some users have asked how much RAM is used when AppleShare is loaded into a Macintosh (used as a workstation) to connect to an AppleShare server, and how much RAM is used when AppleShare PC is loaded into an IBM PC (used as a workstation) to connect to a AppleShare server.

The System Heap RAM on a Macintosh used for AppleShare is 10K. Most of the code required is within the Chooser driver and DA or already available in AppleTalk resources.

The amount of memory used for AppleShare PC is 127,344 bytes without a resident DA or other options.

- For AppleShare PC with the DA resident and the expanded memory option, the amount of memory used is 190,176 bytes.
- For AppleShare PC with the DA resident and no graphics or memory options, the amount of memory used is 200,416 bytes.
- For AppleShare PC with the DA resident and high-resolution graphics support, the amount of memory used is 215,776 bytes.

NOTE: The totals for the PC files loaded into memory include AppleTalk.EXE, ASHARE.COM, MINSES.EXE, REDIR.EXE, DA.EXE, DA.DTA, DA.HLP, and ANET.EXE.

AppleShare PC 1.1 will use about the same amount of RAM as AppleShare PC 1.0. If there is a difference, it will be plus or minus 1K or so.

Not all of these programs are loaded at once. Those that are not loaded have code segments or overlays sharing allocated space.

For this reason, the file size is not the same as the allocated memory size. These numbers represent the allocated total space within memory for the mentioned files.

HyperCard: Damage To Large Stack May Be "Command-Period" Problem

=====

Article Created: 7 April 1988
Article Last Reviewed: 3 June 1992
Article Last Updated: 3 June 1992

NOTE: The inability to compress large stacks was discovered and corrected in versions of HyperCard after release 1.0.1. The problem caused by pressing command-period when creating a new card was discovered and corrected in versions of HyperCard after release 1.1. The following information is for those using previous versions.

Some users have experienced damage to large HyperCard stacks, resulting in inaccessible stacks, and - in cases where the stacks were not backed up - potential loss of valuable data and time.

Damage to a stack may be the result of using the command-period keystroke to stop the creation of a new card. Stacks most susceptible to this problem are those containing "create a card" scripts, some of them written to test HyperCard's card limits. Stopping the creation of a card using command-period prevents HyperCard from completely creating the data structures needed to support the card. This is compounded when you attempt to compact the stack.

After backing up the file, try these methods:

- Launch HyperCard with any stack other than the damaged stack, such as the Home stack. Then, open the damaged stack with the Open Stack option (File menu).
- From the Message box or script, type: "go card 3 of stack 'your stack'".
- From a script, set lockScreen and lockMessages to true; then attempt to go to a specific card.

If any of these suggestions work, you might be able to write a retrieval script that will go from card-to-card within your stack and copy the

contents elsewhere.

If you are not able to display any portion of your stack following the suggestions above, the stack's data structure is damaged to the point of requiring more powerful data recovery tools. FEdit or a similar disk editor may allow you to open your file, then copy and paste that information into another file.

Meanwhile:

1. ALWAYS back up your files regardless of the size or the applications used to create them. Tools, such as Apple's Tape Backup 40SC, make this relatively painless, particularly when you compare that to the time and expense of having to recreate the data when a problem of this nature occurs.
2. DON'T type command-period when creating a new card.
3. Compact your stacks regularly, as often as after every 10 cards when creating or deleting.

Apple Tape Backup 40SC: Won't Back Up Busy Files (9/95)

Revised: 9/20/95
Security: Everyone

Apple Tape Backup 40SC: Won't Back Up Busy Files (9/95)

=====

Article Created: 4 May 1988
Article Reviewed/Updated: 20 September 1995

TOPIC -----

Can files that are in use still be backed up by my 40SC Tape Back-up?

DISCUSSION -----

A file that is in use, whether it is an application you are using, or an open file you are editing/viewing, is marked by the system software as being "busy" and therefore can NOT be backed up by the 40SC Tape Back-up.

To back up these files or applications, close the file and quit the application before running the back-up program.

In addition, the System file, Finder, and other like files in the System Folder on your start-up volume are marked as "busy". To back up system software, you need to start up from a different volume before running the 40SC Tape Back-up application.

Apple IIGS: You Must Optimize Applications for RGB Video Display

=====

This article last reviewed: 7 April 1988

Some users have reported display problems with the Apple IIGS and the RGB monitor. Some packages mentioned included Wizardry, Chuck Yeager's Flight Simulator, Reader Rabbit, and Bismark.

The problems sometimes occur only with text, and sometimes show up as "bleeding" on the video display.

Programs that are written to run on non-RGB systems do not concern themselves with where, or how, the display is generated -- in other words, "video is video" for non-RGB systems.

With RGB video, there are other constraints, and many programs do not adhere to them, even if they are modified to run on the Apple IIGS. Many times the package reads "Runs on the GS in IIe emulation mode", which indicates the video will be normal for composite monitors and NOT optimized for RGB.

This usually indicates that it should be run with the system speed at Normal--not at Fast.

(Wizardry was written for the Apple IIe a number of years ago; Chuck Yeager's Flight Simulator is recent but still written for the Apple IIe -- and is not optimized for RGB.)

When a program is written for use on the Apple IIGS, it is usually optimized for RGB, which looks fine when displayed on composite monitors.

ImageWriter II, LQ Interleaving Problem: An AppleShare Solution

Revised: 11/2/88
Security: Everyone

ImageWriter II, LQ Interleaving Problem: An AppleShare Solution

=====

This article last reviewed: 7 April 1988

The ImageWriter II and ImageWriter LQ interleaving problem (where two or more different printing jobs are interleaved together) is a carry-over from the days of the 128K/512K systems. Because of the limited memory of those systems, it was necessary to spool the file being printed to one page at a time. This meant a multi-page document would be sent as a series of print jobs -- not as one complete job. Software manufacturers knew of this limitation and wrote their applications accordingly.

Many of these manufacturers continue to use the same print routines, with additions for new features, rather than rewrite them to more fully use the features of the drivers.

Print drivers maintain connections with any networked printer for the duration of the current print job. As long as applications still use the older style of one-page-per-job, the interleave problem will continue. Many newer manufacturers are now writing the applications as recommended by Apple in "Inside Macintosh", so the problem is slowly diminishing.

AppleShare Print Server will resolve this problem. It contains a process whereby the user can specify the time-out interval between pages of a print job.

If the time-out is set to 1 minute (for example), any jobs sent by a user, with less than a minute between them, will be printed as one job. However, if a short interval (perhaps 10 seconds) is set, and it takes 15 seconds to send the next page, another user's job could be queued in between the two pages, and the interleave problem would still exist. There is no set value for the time-out feature that will work with every application. The default value is 5 seconds. Some applications may need a higher value if they require more time to set up the print job.

ImageWriter LQ: Why Top Half of Ribbon Wears Faster

Revised: 11/22/91
Security: Everyone

ImageWriter LQ: Why Top Half of Ribbon Wears Faster

=====

This article last reviewed: 7 April 1988

Some users have asked why their ImageWriter LQ printer seems to print only on the top third of the ribbon.

The ImageWriter LQ adjusts the ribbon height with every page it prints, in a four-page cycle. If you print predominantly single- or double-page documents, you will see wear only on the upper half of the ribbon.

You use the ribbon fully only when you print documents of at least four pages. After that, the fifth page uses the same ribbon section as page one, page six the same as two, etc.

LaserWriter Family: Adjusting Default Timeout Values (2/95)

Revised: 2/24/95
Security: Everyone

LaserWriter Family: Adjusting Default Timeout Values (2/95)

Article Created: 5 May 1988
Article Reviewed/Updated: 24 February 1995

TOPIC -----

The following information discusses LaserWriter timeouts and the default values of these timeouts.

DISCUSSION -----

The LaserWriter family has three types of "timeouts" that cancel an existing job on expiration:

- Job timeout: duration time of the job.
- Feed timeout: time allowed to manually feed the paper.
- Wait timeout: time the printer waits for additional input on the current job.

The following are the default values of these timeouts; a PostScript program can be used to change the defaults for a current job, if necessary (see below).

	Job Timeout	Manual Feed Timeout	Wait Timeout
	-----	-----	-----
LaserWriter	0 (never)	60 seconds	30 seconds
LaserWriter Plus (Rev. 38 or before)	0 (never)	60 seconds	30 seconds
LaserWriter Plus (Rev. 47 ROMs)	0 (never)	60 seconds	40 seconds
LaserWriter IINT/NTX	0 (never)	60 seconds	40 seconds
LaserWriter IIIf/IIg	0 (never)	60 seconds	300 seconds

LaserWriter Pro 600/630	0 (never)	60 seconds	300 seconds
LaserWriter PRO 810	0 (never)	60 seconds	40 seconds
Personal LaserWriter NT	0 (never)	60 seconds	300 seconds
Personal LaserWriter NTR	0 (never)	60 seconds	300 seconds
Personal LaserWriter 320	0 (never)	60 seconds	300 seconds
LaserWriter Select 360	0 (never)	60 seconds	300 seconds
LaserWriter Pro 16/600 PS	0 (never)	60 seconds	300 seconds

Note:

Appendix D of "PostScript Language: Reference Manual", available from Addison-Wesley (ISBN# 0-201-10174-2), contains additional information on timeouts and default adjustments.

Changing the timeout is done with the "setdefaulttimeouts" PostScript operator. This operator establishes the default values, job, manual feed, and wait for the three timeouts.

At the beginning of each job, these values are used to initialize the job, manual feed, and wait timeouts. Each parameter must be a non-negative integer denoting the length of a timeout in seconds. The value of 0 indicates that the corresponding timeout should never occur. A PostScript program, like the one that follows, can be sent to the printer to change timeout values.

Caution:

If you choose to use the PostScript code provided in this article, you assume all risks involved in making these changes. PostScript code, if not entered correctly, can place the LaserWriter into a condition requiring service.

```
%=====
% Begin PostScript Code
%
serverdict begin 0 exitserver
statusdict begin
# # # setdefaulttimeouts
end
%
% end PostScript Code
%=====
```

where # # # should be replaced by the job, manual-feed, and wait-timeout values in seconds. For example, if you want to change the manual-feed timeout of the LaserWriter IIg to 120 seconds and keep the other values at their default setting, the PostScript program should look like this:

```
%=====
% Begin PostScript Code
```

```
%  
serverdict begin 0 exitserver  
statusdict begin  
0 120 300 setdefaultttimeouts  
end  
%  
% end PostScript Code  
%=====
```

The PostScript program then can be downloaded to the printer using the
LaserWriter Utility 7.1 (or later).

Apple Personal Modem: Can't Be Used In All Countries

=====

This article last reviewed: 13 April 1988

The Apple Personal Modem can't be used in Australia (or in many other countries).

The modem may tolerate lower foreign voltages (as low as 50 Hz), but this is not the primary problem.

Factors affecting modem operation vary from country to country. Some countries confiscate computer equipment if you are found using a modem within their borders. Other countries allow unrestricted use of modems, but most have their own frequency standards.

The Apple Personal Modem adheres to Bell 103 and Bell 212 standards, but these are U.S. standards -- most other countries do not meet these specifications. There are also different standards for the grade (quality) of phone lines. Modems must be able to use the physical media available in the country of use.

Article Last Updated: 3 June 1992

There are several avenues for a business or other user to make contact with HyperCard programmers and consultants.

A request posted on AppleLink, in the Developer Services or User Groups bulletin board, will reach a wide number of Apple-oriented developers. Also, the readers of these bulletin boards network in turn with an even greater number of potential candidates.

Don't overlook the many electronic services, which include: GEnie, Source, America Online, and CompuServe. Many of the most highly skilled and up-to-date programmers regularly access these services.

Obtaining TCP/IP and PC/IP Protocols for Macintosh and IBM PC

=====

This article last reviewed: 14 April 1988

Some users utilizing NCSA Telnet are interested in running TCP/IP protocols across all their PCs, and have asked if there is a compatible IP version for the IBM PC side.

NCSA Telnet was developed by the National Center for Supercomputer Applications; they have created software for both the Macintosh and the IBM PC.

The IBM software is known as PC/IP. You may contact the Center for more information concerning this package.

For more information, search under: "NCSA".

Moving Apple II DOS 3.3 Data to Macintosh

=====

This article last reviewed: 21 April 1988

If you wish to run Apple II DOS 3.3 files on a Macintosh (512Ke or newer), you must do the following:

1. If the Apple II Plus is the only Apple II available (NOTE: if an Apple IIe is available, see below), then you need:
 - a minimum of 64K in the Apple II Plus
 - one 5.25" drive
 - one 3.5" drive
 - the program "Convert" from a ProDOS System Disk, V1.0, on a bootable 3.5" disk
 - the collected data on a 5.25" disk
- and
- one Macintosh (512Ke, Plus, SE, or II)
 - two disk drives (two 800K floppies or one 800K floppy and a hard drive)
 - Apple File Exchange (on one of the floppies or on the the hard drive).

Once these items are together, follow these steps:

- a. Insert the ProDOS disk in the 3.5" drive and the data disk in the 5.25" drive.
- b. Run "Convert".
- c. Transfer the data ("Convert" defaults to 5.25" --> 3.5").
- d. Eject the 3.5" disk, which now has the data converted to ProDOS format.

- e. Launch Apple File Exchange on the Macintosh.
- f. Insert the ProDOS 3.5" disk in the Macintosh drive. (AFE displays its disk in one window and the ProDOS disk in another.)
- g. Select the data file from the ProDOS disk, and click the transfer button.

2. If there is an Apple IIe available, you need:

- a minimum of 128K in the Apple IIe
- one 5.25" drive
- one 3.5" drive
- System Utilities 3.0 on a bootable 3.5" disk
- the collected data on a 5.25" disk

and

- one Macintosh (512Ke, Plus, SE, or II)
- two disk drives (two 800K floppies or one 800K floppy and a hard drive)
- Apple File Exchange (on one of the floppies or on the the hard drive).

Once these items are together, follow these steps:

- a. Insert the ProDOS disk in the 3.5" drive and the data disk in the 5.25" drive.
- b. Run System Utilities (labeled SYSUTIL.SYSTEM).
- c. Copy the data file from the 5.25" disk to the 3.5" disk using "Copy Files".
- d. Eject the 3.5" disk, which now has the data converted to ProDOS format.
- e. Launch Apple File Exchange on the Macintosh.
- f. Insert the ProDOS 3.5" disk in the Macintosh drive. (AFE displays its disk in one window and the ProDOS disk in another.)
- g. Select the data file from the ProDOS disk, and click the transfer button.

Using either method, the data from the test instrument is now a Macintosh text file. Once in the Macintosh text file format, it can be loaded into a variety of Macintosh applications.

Macintosh II: Specifications (Discontinued 1/90)

Article Created: 29 April 1988
Article Last Reviewed: 29 June 1992

TOPIC -----

This articles gives technical specifications for the Macintosh II.

DISCUSSION -----

MICROPROCESSOR

- MC68020, 32-bit architecture, 15.6672MHz clock frequency
- MC68881 floating-point unit (IEEE standards)
- Optional 68851 PMMU (Paged Memory Management Unit)

MEMORY

- 1MB RAM, expandable to 68 MB on board; expandable to 2 GB in NuBus slots; 120ns or faster SIMMs.
- 256K ROM

DISK DRIVES

- Built-in 800K floppy disk drive; support for one additional 800K floppy disk drive. Support for 1.4MB floppy drive with either Macintosh IIfx or Macintosh IIfx upgrade kits.
- Support for one internal SCSI device

DISPLAY

- Support for up to six Nubus display cards

INTERFACES

- Two mini-circular 8 serial (RS-422) ports
- One DB-25 SCSI port
- Two Apple Desktop Bus ports
- Six NuBus internal slots supporting full 32-bit address and data lines

MOUSE

..TIL02884-Macintosh_II-Specifications_Discontinued_1-90_(193_Mac).pdf

- Apple Desktop Bus Mouse; mechanical tracking, optical shaft, or contact encoding

SOUND GENERATOR

- Custom sound chip drives stereo miniature phone jack headphones or stereo equipment.

CLOCK/CALENDAR

- Custom chip with long-life lithium battery

ELECTRICAL REQUIREMENTS

- Line voltage: 90 to 140 VAC and 170 to 270 VAC, automatically configured
- Frequency: 48 to 62 Hz
- Power: 230 watts, not including monitor power

OPERATING ENVIRONMENT

- Operating temperature: 10 to 35 degrees C (50 to 95 degrees F)
- Storage temperature: -40 to 47 degrees C (-40 to 110.6 degrees F)
- Relative humidity: 5% to 95% noncondensing
- Maximum altitude: 3,048 m (0 to 10,000 ft)

SIZE AND WEIGHT

- Main unit
 - Height 14.0 cm (5.5 in)
 - Width 47.4 cm (18.7 in)
 - Depth 36.5 cm (14.4 in)
 - Weight 10.9 kg (24 lbs)*
- Mouse
 - Height 2.8 cm (1.1 in)
 - Width 5.3 cm (2.1 in)
 - Depth 9.7 cm (3.8 in)
 - Weight .17 kg (6 oz.)

Hard Disk File Recovery Suggestions

Revised: 5/5/88
Security: Everyone

Hard Disk File Recovery Suggestions

=====

This article last reviewed: 28 April 1988

Some people have asked about how to salvage files when a backup that uses the HDBackup program to back up a large file (more than 800K) does not restore properly.

One problem specifically mentioned occurred when the backup itself had been completed without any problems, but when an attempt was made to restore the file, a "Disk Full" message appeared after the last disk was inserted.

Unfortunately, recovering the data in such a situation can be difficult and time-consuming; the recovery effort is compounded by the file being split between two or more diskettes.

Usually, if the "restore from backup" fails, each diskette containing the backed up information can be inserted, and each file copied with the Finder. When the back-up data is split among many diskettes, recovering the data depends on the type of file, the file format, and your persistence.

Here are some suggestions to aid recovery:

1. Make a copy of the files.
2. Recovering a file may be as easy as launching an application, then choosing to display the file. Since the file is divided between two diskettes, it needs to be rejoined using Copy and Paste.
3. If you're unable to open the file, consider changing the file type with ResEdit to an appropriate file type, such as text if it is a word processing file. This may enable you to open the files separately and rejoin them using a text editor or word processor.
4. If the file is a spreadsheet or any "text-based" type of file, you should still consider changing the file type to text. This may allow you to open the file -- but would require more work to re-establish the

delimiters before exporting it back into the original file type.

If you are not able to recover any portion of the files by following the suggestions above, then important file structures are either incomplete or missing -- which means that more powerful data recovery tools are required. FEdit or a similar disk editor may allow the files to be opened, then copied and pasted into another file.

(NOTE: Running under MultiFinder will speed up the copying and pasting process.)

More difficult recovery procedures involve using file format information and a disk editor to perform specific repairs to the files -- namely, to decipher and extract recoverable data. If the file is compressed or encrypted, file recovery is likely to be very difficult. You must first decipher the scheme used, then decipher or translate the data, byte by byte. Getting access to the file format is essential -- and you will need lots of time and patience as well.

LaserWriter IINT/NTX: Default Values For Font Cache

Revised: 9/22/89
Security: Everyone

LaserWriter IINT/NTX: Default Values For Font Cache

=====

This article last reviewed: 29 April 1988

Default values are set for the font cache in the LaserWriter IINT and LaserWriter IINTX, as well as for the display list and communications buffer. Font cache and display list sizes are persistent parameters and can be reset.

The default values are (in hex):

	2MB or less	3MB or less	3MB or more
Font Cache size	\$286000	\$330000	10% RAM size
Display List size	\$10000	\$150000	10% RAM size

These parameters permit setting the RAM allocation in the LaserWriter IINTX.

(IMPORTANT NOTE: If the RAM allocations are set incorrectly, it could have a VERY BAD effect on the operation of the printer. Do not adjust these unless you know what you are doing, or have consulted with someone who does!)

Normally, these values are set to 0 in the EEROM (ZPRAM), which tells the printer to calculate the necessary sizes based on RAM size.

Also, a change has been made to the operation of the font cache in more recent LaserWriters. Formerly, there was a single limit on the number of bytes occupied by a character in the cache; a character larger than the limit would not be cached. Now there are two cache thresholds, an upper one and a lower one.

If a character is larger than the upper threshold (as determined by the bounding box specified to setcachedevice), the character is still not cached; if smaller, it is.

Once the character is cached, if it's larger than the lower threshold it is compressed; if not, it is stored as a full-pixel array.

Foreign File Formats: AppleSingle and AppleDouble (9/94)

Revised: 9/21/94
Security: Everyone

Foreign File Formats: AppleSingle and AppleDouble (9/94)

=====

Article Created: 29 April 1988
Article Reviewed/Updated: 21 September 1994

TOPIC -----

Apple provides two standards for representing files on foreign file systems. The goal is to preserve all attributes of the file's home file system on file systems that don't otherwise support the same attributes.

DISCUSSION -----

Experience indicates that one format is inadequate to cover all cases. Two closely related formats, however, can serve most needs. The primary reason for developing these formats is to allow storage of Macintosh files on file systems that don't support the notion of two forks. However, the proposed formats are general enough for use in representing a file from any file system on any other file system.

AppleSingle

AppleSingle format keeps all contents and attributes of a file in a single file on the foreign file system. For example, both forks of a Macintosh file, the Finder information and associated icons, and so on, are arranged in a single file with a simple structure. The intention is to use this format primarily as a storage format; that is, for Macintosh files that must be stored on a foreign file system and later reconstructed into true Macintosh files.

An AppleSingle file contains a header followed by data. The header consists of several fixed fields and a list of "entry descriptors," each pointing to an "entry." Apple defines these standard entries as Data Fork, Resource Fork, Real Name (name in the home file system), Comment, Icon, and File Info. Each entry is optional and may or may not appear in the file.

AppleDouble

AppleDouble format is more appropriate for applications in which the users of the foreign file system want to modify the contents of the file. Since most Macintosh applications keep the file data in the data fork, AppleDouble format saves the contents of the data fork in one file, and all other file attributes are kept in a separate file.

AppleDouble format is the same as AppleSingle format, except that the data is kept in a separate foreign file. The file containing the data fork is called the "AppleDouble Data File," and the other file is called "AppleDouble Header File."

The AppleDouble Data file contains only the standard Macintosh data fork, with no extra header. The AppleDouble Header File has exactly the same format as the AppleSingle file, except that it DOESN'T contain a data fork entry.

Applications

- Standard for Transferring Files Between Host Computers (Interhost)
For example, Macintosh files could be shipped easily and completely among different systems if they all understood one of these common formats. Any existing e-mail system or file transfer utility could be used without modification.
- Standard for Operating on Foreign Files within a Single Host (Intrahost)
A possible example would be UNIX applications that can build and manipulate Macintosh resource forks (perhaps a cross-development system). If host computer users want to write Macintosh-aware applications, they can use a common storage format, such as AppleSingle and AppleDouble.

AppleSingle and AppleDouble Specifications

There is a document titled "AppleSingle/AppleDouble Formats for Foreign Files Developer's Notes." It describes version 2 of the AppleSingle/AppleDouble file formats. These formats were originally developed for storing Macintosh files on an A/UX file system, but have since been adapted for storing files from various operating systems (not just Macintosh) on foreign file systems.

You can obtain a printed version of this document from APDA. You can also find this document in the Technical Information Library under the title "AppleSingle/AppleDouble Formats: Developer's Note".

How To Prevent Switch-Launching Between Floppy Disks

Revised: 9/16/88
Security: Everyone

How To Prevent Switch-Launching Between Floppy Disks

=====

This article last reviewed: 29 April 1988

Some users have asked if there is a way to prevent switch-launching between floppies on a floppy-based system.

The "Technical Introduction to the Macintosh Family" states: "You can prevent this switch-launching by holding down the Option key when you start the application."

Actually, switch-launching is either prevented OR allowed by this procedure, depending on the kind of disks in the system.

Hard Disk Systems

Switch-launching is generally PREVENTED in a hard disk system. To force a switch-launch:

1. Hold down the Option and Command keys while opening an application.
2. Set the Finder Flags for the application to "Always switch-launch" (Get Info on the file using ResEdit).

Floppy Disk Systems

In floppy-based systems, the system generally switches to the System files on the diskette that contains the application being opened.

Holding down the Option key while opening an application on a floppy-based system will NOT prevent switch-launching (as is incorrectly stated in the "Technical Introduction to the Macintosh Family".) Therefore, to prevent switch-launching to a diskette on a floppy-based system:

1. Remove the System Folder.

2. Place either the System file or Finder -- but not both -- into another folder, or at root.
3. Use MultiFinder, which prevents switch-launching (if there is sufficient RAM to support both MultiFinder and the applications).

Macintosh Plus Doesn't Provide Termination Power

Article Created: 29 April 1988
Article Last Reviewed: 24 July 1992
Article Last Updated:

TOPIC -----

Some users have experienced problems with SCSI hard drives that don't start up on a Macintosh Plus if they are the only SCSI device, but the same drive may work correctly when hooked up to a Macintosh SE or Macintosh II.

DISCUSSION -----

This is usually a termination problem. That is, if you have correctly configured your SCSI bus with the proper number of terminators (you can refer to the SCSI Cable System manual, Apple Part #030-2042-B), the problem probably lies with your hard disk's inability to provide termination power to the terminator(s).

The drive doesn't work when connected to a Macintosh Plus because the Macintosh Plus does NOT provide termination power. The same drive works when connected to a Macintosh II or Macintosh SE -- or when another SCSI device is connected to the bus -- because these devices supply termination power.

Sometimes SCSI peripherals will work without proper termination -- usually only when the data lines are "clean" enough to support communication. This cannot be relied on to continue; therefore, you should:

- Repair the drive so that it provides termination (as it should if it were working correctly.)

OR

- Connect another SCSI device providing termination power.

OR

- Use this hard disk on another system that provides termination power, such as a Macintosh II or Macintosh SE.

PMMU's Advantages in a Multitasking Operating System

=====

Article Created: 29 April 1988
Article Last Reviewed: 20 July 1992
Article Last Updated: 20 July 1992

TOPIC -----

Some users have asked whether the Macintosh II computer's PMMU (Paged Memory Management Unit) -- which handles the translation from 24 bits to 32 bits, and supports the 32-bit operating system -- provides any special advantages, such as speed.

DISCUSSION -----

The 68851 PMMU does not provide any advantage over the standard HMMU when used with System 6. The HMMU and PMMU BOTH handle the 24-bit-to-32-bit translation, which allows the existing Macintosh software to run on a Macintosh II. There is also no increase in speed when using the PMMU instead of the HMMU.

However, the advantages of PMMU become apparent when used with multitasking operating systems, such as UNIX and System 7. Such systems use virtual memory and require a logical-to-physical translation of an address from the processor; this is where the 68851 PMMU becomes an absolute necessity.

For more information on the advantages of the 68851 PMMU in a multi-tasking, 32-bit operating system, see: "Technical Introduction to the Macintosh Family" (ISBN#: 0-201-17765-X) page 206.

Apple IIGS: How To Correct Point Size Printing Problems

=====

This article last reviewed: 12 May 1988

Currently, there is a font size printing problem with the Apple IIGS with an ImageWriter II when using various programs, including Activision's Writer's Choice Elite. The problem is that the fonts that come with the program do not print the proper point sizes. The 8-point size measures nearer to 12 points, and so on. (These are apparently Apple fonts, licensed by Activision.) Until Apple releases new system fonts, you can choose either of two solutions:

- The better solution is to make sure you get the Apple IIGS System Disk, Version 3.1 or later. It contains the Page Setup Dialog version 1.3 or later. Starting with version 1.3, the Page Setup Dialog contains an area for vertical sizing offering either normal or condensed print. Select Normal for an exact duplicate of the font's screen size. Select Condensed for the selected point size.
- The other solution is to print in Draft and use the built-in NLQ mode of the ImageWriter II. Unfortunately, this method creates a problem with the spacing between words -- just like on the Macintosh.

TOPIC -----

I have a problem that occurs on a Macintosh II with a color monitor and a video expansion card: Vertical green lines appear on the lower third of the screen when you select the 256-bit mode from the control panel. However, when in the 16-bit mode, the monitor behaves normally.

DISCUSSION -----

The problem may be a video RAM problem. Try replacing the eight extended video RAM chips with known, good video RAM. If the problem persists, you may need to replace a defective video card.

A/UX: Source of Keyboard Delay During Log-In

=====

Article Created: 10 May 1988

Article Change History

08/31/92 - REVIEWED
o For technical accuracy.

TOPIC -----

When A/UX starts up, there's a delay in the keyboard response: it takes a couple of keystrokes before anything appears in response to the "login:" prompt. Here's why: during the log-in sequence ("getty" to "login"), /etc/getty waits one second after issuing the following log-in prompt message:

Apple Computer, Inc. A/UX

login:

DISCUSSION -----

This one-second delay keeps noise from being passed to the "login" process, ensuring that phone lines are clean before dialing.

To avoid the keyboard delay, just wait one second before responding to the log-in prompt. It isn't necessary to wait one second after the other "login" or "Password" prompts, because they're generated by the "login" process not the "getty" process.

08/31/92 - REVIEWED
• For technical accuracy.

TOPIC -----

What is the official name of the X Window System?

DISCUSSION -----

According to its developers, the official names are:

- X
- X Window System
- X Version 11
- X Window System Version 11
- X11

Note that the phrases "X.11", "X-11", and "X-Windows" are not included; they SHOULD NOT be used to describe the X Window System.

X Window System: Some Compatibility Questions

Revised: 9/8/92
Security: Everyone

X Window System: Some Compatibility Questions

Article Created: 10 May 1988
Article Last Reviewed: 10 August 1992
Article Last Updated:

TOPIC -----

Compatibility with X means that the client-side application and the X display server communicate according to the X Version 11 protocol, and that the server correctly implements the drawing (output) semantics and delivers events (input) as specified in that protocol. The X protocol is the communication language used between the X client and the X server. The X server listens to display instructions sent by the client according to the protocol and responds by drawing on the screen and returning events (like keystrokes and mouse movements).

Following are some questions and answers about X Window System compatibility.

DISCUSSION -----

Is X Window System Available on any Machine NOT Running UNIX?

The majority of X implementations are for UNIX systems. However, there are other (compatible) implementations that run on VMS, Apollo DOMAIN, and others. When using a true multitasking operating system, an X client (like an engineering design application) can be run on the same CPU as the X display server. In fact, this is the usual pattern for using X: display server and multiple clients running on the same (multitasking) CPU.

Does Compatibility Mean the Macintosh OS Being Able Run to Window X?

You can also run an X display server on a single-user operating system, such as the Macintosh OS or MS-DOS. These implementations require all the X client applications to be run remotely. Some terminal manufacturers (Wyse is one example) have produced intelligent terminals that operate as X

display servers. (These terminals must have a powerful, dedicated CPU, buffering capabilities, and some form of networking built in.)

Can a MacWorkStation-to-X Window System Interface Be Written?

An X server and a remote X client application communicate over a network using a "reliable byte-stream" built on top of a network protocol, such as TCP-IP or DECNet. The same kind of mechanism is used by MacWorkStation to communicate with an IBM mainframe (but the protocol used and many other details differ from X).

The X protocol provides for vendor-specific extensions (a trap door), which allows clients to access special functions in the server. It might be possible for a Macintosh-based X server to offer an extension that offers clients use of Macintosh Toolbox components (like MacWorkStation), but we don't know of any plans to implement such an extension.

Is X Window System like PostScript?

X and PostScript are similar, because they both are used to generate graphic images on bit-map devices (in this sense, QuickDraw is also similar). However, X and PostScript have very different "imaging models." X regards the screen as a rectangular collection of pixels--each may be individually addressed by giving its horizontal and vertical coordinates (like QuickDraw). Lines, curves, and shapes are specified in terms of these device-dependent coordinates.

PostScript, on the other hand, hides many of the device-dependent details (like discreteness of pixels) and gives the programmer the illusion of painting on a canvas in any convenient coordinate system. The PostScript model is, in many ways, richer and easier to use. In addition, PostScript is a true programming language and allows for concise and compact expression of complicated graphic images.

The Sun NeWS window system is based on PostScript. A NeWS application is a collection of PostScript procedures that are sent to a NeWS server (perhaps remotely via a network connection). The server interprets the PostScript procedures and renders graphics in a window on the display's bit-map screen. NeWS extends PostScript by allowing interactive input: the PostScript procedures can respond to user input--keystrokes, mouse motion, and mouse clicks. Some of NeWS is written in PostScript (after all, PostScript is a programming language). In particular, the NeWS window manager is a PostScript procedure.

How Is X Window System Comparable to Display PostScript?

Display PostScript (licensed by Adobe) lets a PostScript procedure render graphics on a bit-map screen (in the same manner as a LaserWriter with its built-in PostScript lets a PostScript procedure render graphics on a sheet of paper). Display PostScript differs from NeWS in that it does not take into account interactive input. X and Display PostScript can be used together: Display PostScript is a front end that accepts a client's PostScript procedure and then issues commands to X causing the appropriate

graphics to be drawn in an X window.

Macintosh 128K and 512K: Upgrade Paths

Revised: 5/11/89
Security: Everyone

Macintosh 128K and 512K: Upgrade Paths

=====

This article last reviewed: 10 May 1988

Macintosh 128K

To upgrade a 128K Macintosh to a Macintosh Plus, a Level I Service Technician installs both:

- M2516 Macintosh Plus Disk Drive Kit, and
- M2518 Macintosh Plus Logic Board Kit (128K)

The M2519 Keyboard is optional.

Macintosh 512K

The Macintosh 512K can be upgraded to three different configurations:

Option 1 - Macintosh 512Ke

Option 2 - Macintosh Plus with a Macintosh 512K keyboard (no numeric pad)

Option 3 - Macintosh Plus with a Macintosh Plus keyboard (includes the numeric pad)

Option 1

To upgrade a Macintosh 512K to the Macintosh 512Ke, a Level I Service Technician installs a M2516 Macintosh Plus Disk Drive Kit. This kit contains the 128K ROMs and an internal 800K floppy disk drive (they replace the Macintosh 512K's 64K ROMs and internal 400K floppy disk drive).

Option 2

To upgrade a Macintosh 512K to a Macintosh Plus (without a numeric pad), a Level I Service Technician does the Macintosh 512K-to-Macintosh 512Ke upgrade first; that is, installs the 800K disk drive. Next, the technician installs a M2518 Macintosh Plus Logic Board Kit (512K) and inserts the 128K ROMs in the Macintosh Plus Logic Board. The result is a Macintosh Plus with the Macintosh 512K keyboard.

Option 3

To upgrade a Macintosh 512K to a Macintosh Plus (with numeric pad), after the Service Technician installs both M2516 and M2518 (as in Option 2), a M2519 Macintosh Plus Keyboard is plugged in. The result is a full-featured Macintosh Plus.

Using an External 800K Drive With a Macintosh 512K

An external 800K drive can be used with a Macintosh 512K that hasn't been upgraded to a Macintosh 512Ke or Macintosh Plus, provided the system file named HD20 Startup is in the System Folder. HD20 Startup was used before the HFS (128K) ROMs were introduced, to allow connection of the original non-SCSI HD20. This system file also works with 800K floppy drives on a Macintosh 512K.

Part Numbers

M2516 Macintosh Plus Disk Drive Kit
M2518 Macintosh Plus Logic Board Kit (512K)
M2518 Macintosh Plus Logic Board Kit (128K)
M2519 Macintosh Plus Keyboard

MouseText: Apple IIC Tecnical Reference Manual Errata

Revised: 5/23/88
Security: Everyone

MouseText: Apple IIC Tecnical Reference Manual Errata

=====

This article last reviewed: 13 May 1988

The Apple IIC Technical Reference Manual (ISBN#: 0-201-17752-8) shows, on pages 90 and 91, a chart of Apple IIC MouseText Characters. The MouseText equivalents for F and G are shown as four horizontal lines, whose purpose is to make window title bars. This is not correct. On an Apple IIC or Apple IIe (either enhanced beige or platinum), the MouseText characters for F and G are the two halves of the "running man" character.

The horizontal line characters are available only in the Apple IIGS MouseText character set. There is no ROM upgrade to add these new characters to an Apple IIe or Apple IIC.

A/UX: Problem With atan2 Function (9/94)

Revised: 9/20/94
Security: Everyone

A/UX: Problem With atan2 Function (9/94)

Article Created: 17 May 1988
Article Reviewed/Updated: 20 September 1994

TOPIC -----

The math library function atan2 gives an incorrect answer for the arguments (-1,0). A/UX returns 0; it should return 3.141593 (pi).

This problem has been fixed in A/UX 2.0.1 and 3.0.

DISCUSSION -----

Here's a sample program:

```
#include<math.h>
main()
{
printf("atan2( 0, 1) = %9.6f\n", atan2( 0., 1.));
printf("atan2( 1, 0) = %9.6f\n", atan2( 1., 0.));
printf("atan2( 0,-1) = %9.6f\n", atan2( 0.,-1.));
printf("atan2(-1, 0) = %9.6f\n", atan2(-1., 0.));
}
```

This program returns:

```
atan2( 0, 1) = 0.000000
atan2( 1, 0) = 1.570796
atan2( 0,-1) = 0.000000
atan2(-1, 0) = -1.570796
```

The result SHOULD be:

```
atan2( 0, 1) = 0.000000
atan2( 1, 0) = 1.570796
atan2( 0,-1) = 3.141593
atan2(-1, 0) = -1.570796
```

This anomaly affects the conversion of rectangular-to-polar coordinates, a common use of the atan2 function.

A/UX: Problem With NaN, printf

=====

Article Created: 17 May 1988

Article Change History

08/27/92 - REVIEWED
o For technical accuracy.

TOPIC -----

The IEEE floating point format used by the Macintosh II allows these special floating values:

- NaN (Not-a-Number)
- +infinity
- -infinity

DISCUSSION -----

These are created by certain math library functions. For example, `log(0)` is `-infinity`. The `printf(3s)` C library functions should give these values special treatment; that is, print them as special strings. Instead, passing the value as a double prints the numerical value of `-HUGE`; passing the value as a float gives segmentation violations.

Here's a sample program:

```
#include<math.h>
main()
{
    double d;
    float f;
    d = log(0.);
    printf("double: %g\n", d);
    f = d;
    printf("float: %g\n", f);
}
```

```
}
```

On A/UX, this program returns:

```
double: -1.79769e+308
Floating exception (core dumped)
```

For comparison, on SunOS, it gives the right answer except for the sign:

```
double: Infinity
float:  Infinity
```

On IBM AIX, it returns:

```
double: -INF
float:  -INF
```

The results with NaN are similar.

MS-DOS Filename Conventions: AppleShare V2.0 Same As V1.1

Revised: 5/24/88
Security: Everyone

MS-DOS Filename Conventions: AppleShare V2.0 Same As V1.1

=====

This article last reviewed: 5 May 1988

Under AppleShare 1.1, an MS-DOS user sees a modified version of any name over eight characters; for example:

Macintosh volume name:	Oxford Blues
AppleShare PC name:	!Oxford .Blu

Some users have asked if AppleShare 2.0 lets the administrator determine the volume names that the PC sees -- that is, make it possible to assign names that are different from the Macintosh names, but readable by MS-DOS -- or if not, whether there is any way to make the names easier to read and type WITHOUT constraining original volume names to eight characters or less?

This problem occurs because of file-naming constraints in MS-DOS, which allow only a maximum of eight characters with a three-character extension (such as 12345678.123) for file names. The Macintosh and AppleShare (1.1 or 2.0) both allow filenames up to 31 characters in length.

Although AppleShare allows filenames to be 31 characters long, it also stores the filenames as "short names", which adhere to the MS-DOS file-naming conventions. These "short names" are used when an MS-DOS machine accesses files from an AppleShare server that have names longer than eight characters. These "short names" are generated by a predefined algorithm of the characters in the actual name, and CANNOT be controlled by the system administrator.

This is true for both AppleShare versions 1.1 and 2.0. If file names must be easy to read and type, assign names of eight characters or less.

AppleColor Hi-Res Monitor Needs Composite TTL Sync

Revised: 7/7/88
Security: Everyone

AppleColor Hi-Res Monitor Needs Composite TTL Sync

=====

This article last reviewed: 6 May 1988

A user asks whether the Macintosh II High-Resolution Color Monitor requires the external sync (TTL sync) signal that comes off the Macintosh II Video Card on pin 3, or does the monitor derive the sync from the green video -- that is, does the monitor work with just red, green, and blue signals?

The AppleColor High-Resolution RGB Monitor requires the composite TTL sync from pin 3 -- the AppleColor Monitor CANNOT use the composite sync from the analog green channel with composite sync (pin 5).

The necessary connections are shown below:

AppleColor Monitor		Apple Video Card
1 Red video return	---->	1 Ground
2 Red video	---->	2 Analog red channel
3 Composite TTL sync	---->	3 Composite TTL sync
4 Composite sync return	---->	4 Ground
5 Green video	---->	5 Analog green channel with sync
6 Green video return	---->	6 Ground
7 (not used)		7 (not used)
8 (not used)		8 (not used)
9 Blue Video	---->	9 Analog blue channel
10 (not used)		10 (not used)
11 (not used)		11 Ground
12 (not used)		12 Analog green channel with sync (not used)
13 Blue video return	---->	13 Ground
14 (not used)		14 Ground
15 (not used)		15 (not used)

HyperCard 1.1: Workaround For Delete Card Problem

Revised: 10/18/88
Security: Everyone

HyperCard 1.1: Workaround For "Delete Card" Problem

=====

This article last reviewed: 6 May 1988

Users of HyperCard 1.1 stacks find that an attempt to do a "delete card" sometimes calls up an error message -- "Unexpected error 54321" -- and a "sorry" button, which quits HyperCard. (This problem does not occur with HyperCard 1.0.1.)

This IS a problem with HyperCard 1.1: if there is an "onOpen Card" handler on the card after the one you are attempting to delete, or an "onDelete Card" handler in the script of the card you are trying to delete, when you try to delete that card, you receive the error. If there is an "onDelete Card" or "onOpen Card" handler in the background -- or stack -- script, you also get the error when you try to delete the card.

An example of this can be seen in any HyperCard 1.1 Home stack. When trying to delete the card titled, "Look for Documents In:", you get the error. In the script for the last card in the Home stack, there is an "onOpen Card" section of code.

The Workaround

Insert two hyphens and a space before each line of the above-mentioned code. You can then delete that card.

ImageWriter LQ Doesn't Have 50% Reduction Capability

Revised: 5/24/88
Security: Everyone

ImageWriter LQ Doesn't Have 50% Reduction Capability

=====

This article last reviewed: 6 May 1988

Some users have asked why the ImageWriter LQ options for reduction are 33% and 66% only, instead of a 50% reduction as with the ImageWriter II.

The reason is this: the Macintosh screen is 72 dpi, and the ImageWriter LQ in Best mode prints at 216 dpi. If you take the image on the screen, and do not scale it in any way before sending it to the ImageWriter LQ (printing at 216 dpi), the output reduction is 33% -- that is, 72/216.

If you scale this screen image by a factor of two and print it on the same printer at 216 dpi, the result is a 66% reduction -- or, 144/216.

This is the difference from the ImageWriter II, which prints at 144 dpi. The unscaled screen image, when sent to the printer, automatically prints at 50% reduction -- at 72/144.

The reduction modes chosen for the ImageWriter II and ImageWriter LQ printers represent the "natural" reduction modes for each, depending on the printer resolution, and the way the ImageWriter printer drivers handle bit-map printing.

ImageWriter Custom Characters: How To Get Rid Of Underlines

Revised: 5/24/88
Security: Everyone

ImageWriter Custom Characters: How To Get Rid Of Underlines

=====

This article last reviewed: 10 May 1988

Some users have discovered that when they try to create custom characters with the ImageWriter I and II printers, the resulting character is always underlined -- whether they want it that way or not.

The Apple ImageWriter I and ImageWriter II printers -- as well as the Apple Dot Matrix Printer -- have special modes that allow them to generate custom-design characters. For the most definition on each character, it is useful to control all eight data bits sent to the printer.

This Applesoft BASIC program has been tested for the underlining problem, and will work correctly (that is, the character will appear as desired):

```
10 D$ = CHR$(4)
20 FOR I = 768 TO 773: READ J: POKE I,J: NEXT I
30 PRINT D$;"PR#1"
40 FOR I = 1 TO 14: READ J: POKE 769,J: CALL 768: NEXT I
50 PRINT CHR$(27)"*&&&" CHR$(27)"$"
60 PRINT D$;"PR#0"
70 DATA 169,4,76,237,253,96
80 DATA 27,45,27,73,166,71,0,72,72,126,72,72,0,4
```

Line 20 reads the data from line 70, and POKES a machine language routine into the computer. Line 30 activates the printer. Line 40 reads the data from line 80, which is a string of data defining a custom character (in this case, the plus/minus character shown in the ImageWriter manual). It is defined using eight bit data where all eight bits are required. Line 50 uses the custom character, and line 60 returns the output to the screen.

For more information on these procedures, see pages 69 and 70 of the ImageWriter User's Manual, Part 1 (Apple Part #030-0730).

Command-Period Doesn't Cancel Print to LaserWriter IISC

Revised: 5/24/88
Security: Everyone

Command-Period Doesn't Cancel Print to LaserWriter IISC

=====

This article last reviewed: 10 May 1988

When using the LaserWriter IISC, printing within an application (such as MacPaint) that contains a dialog box requiring the "command-period" to stop printing, you may experience this problem: the "command-period" does NOT stop or interrupt the printing.

However, if you are printing within an application that uses a dialog box with a "cancel" button, the cancel button DOES stop the printing.

This is a problem characteristic of the LaserWriter IISC driver, not the PostScript printer drivers. Currently, you CANNOT cancel most print jobs when programs display a printing message stating "To cancel, hold down the command key and type a period (.)"

LocalTalk PC Card: Compatibility With MS-DOS Systems

=====

This article last reviewed: 11 May 1988

Apple's LocalTalk PC card is compatible with:

- IBM PS/2, models 25 and 30
- PC XT
- PC AT

and most clones, all of which use the PC bus.

Apple's LocalTalk PC card is NOT compatible with:

- IBM 3270 Communication card
- PCs using MicroChannel bus architecture
- PCs using OS/2

TOPS "FlashCard" works with the 3270 Communication card and may be a viable workaround.

Tangent Technologies has announced a card that works with PCs having the MicroChannel bus architecture.

For more information, search under: "Tangent Technologies" and "TOPS"

AppleShare PC: Memory Use

Revised: 5/24/89
Security: Everyone

AppleShare PC: Memory Use

=====

This article last reviewed: 11 May 1988

Some users have asked about the amount of RAM that AppleShare PC occupies in a PC.

The amount of memory used is:

- | | |
|---|---------------|
| - No resident DA or other options: | 127,344 bytes |
| - DA resident with expanded memory option: | 90,176 bytes |
| - DA resident (no graphics or memory options): | 200,416 bytes |
| - DA resident and high-resolution graphics support: | 215,776 bytes |

The totals for the PC files loaded into memory include ATALK.EXE, ASHARE.COM, MINSES.EXE, REDIR.EXE, DA.EXE, DA.DTA, DA.HLP, and ANET.EXE.

Not all of the programs are loaded at once. Those that are not loaded have code segments or overlays sharing allocated space. For this reason, the file size is not the same as the allocated memory size. These numbers represent the allocated total space within memory for the mentioned files.

HyperCard: Using It To Control A Multimedia Presentation

Revised: 5/31/89
Security: Everyone

HyperCard: Using It To Control A Multimedia Presentation

=====

This article last reviewed: 10 February 1989

An interactive multimedia presentation (such as one using 35mm slide projectors, cassette recorders, and lights) can be controlled using the Apple MIDI device, the J.L. Cooper Electronics MIDI Mute, and the XCMD from the HyperMIDI stack.

The J.L. Cooper MIDI Mute contains eight reed relays in one unit that can be controlled with the MIDI XCMD found in the HyperMIDI stack. Apple's MIDI device is the interface between the Macintosh and the J.L. Cooper MIDI Mute.

The control of a particular audio/visual device depends on that device's control interface. For example, the wired remote control found with slide projectors can be easily replaced with the MIDI Mute. The AC power to that same slide projector, however, will require a custom-built power switch that connects to the MIDI Mute. An infrared remote is not a trivial project.

(NOTE: Some knowledge of MIDI codes is also required to complete this system.)

List Of Font ID Numbers (Apple No Longer Assigns Them)

Revised: 10/18/88
Security: Everyone

List Of Font ID Numbers (Apple No Longer Assigns Them)

=====

This article last reviewed: 12 May 1988

Some users have asked about importing fonts under ID numbers already reserved to Apple fonts (although not necessarily filled by existing fonts).

The Font Manager chapter of Inside Macintosh, Volume IV (Apple Part #030-1389-A), states that font family numbers 0 through 127 are reserved for Apple's use, and numbers 128 through 255 are assigned by Apple for fonts created by software developers.

This is no longer true: Developer Technical Support does NOT assign font family numbers.

When you copy a font into the System file (using the Font/DA Mover), and there is an ID number conflict, the ID number of the font being copied is changed.

Here is a list of fonts and their ID numbers:

New York	ID = 2	Geneva	ID = 3
Monaco	ID = 4	Venice	ID = 5
London	ID = 6	Athens	ID = 7
San Francisco	ID = 8	Toronto	ID = 9
Cairo	ID = 11	Los Angeles	ID = 12
Times	ID = 20	Helvetica	ID = 21
Courier	ID = 22	Symbol	ID = 23
Taliesin/Mobile	ID = 24		

These are the ID numbers for the LaserWriter Plus fonts:

Zapf Dingbats	ID = 13	Bookman	ID = 14
Helvetica Narrow	ID = 15	Palatino	ID = 16
Zapf Chancery	ID = 18	Avant Garde	ID = 33
New Century School Book	ID = 34

AppleShare 1.0, 1.1; LaserShare: How to Upgrade

=====

This article last reviewed: 20 May 1988

Two upgrades are available:

- You can upgrade AppleShare 1.0 or 1.1 to the new AppleShare File Server Version 2.0.
- You can also upgrade your copy of LaserShare to AppleShare Print Server.

Price

The upgrades are free to customers who purchased AppleShare or LaserShare on or after March 1, 1988. Product purchased before March 1, 1988 can be upgraded for \$50.00 for each copy of AppleShare or LaserShare.

How to Upgrade

The upgrade form was sent out in the March 20, 1988 AppleGram. All upgrades must use the official upgrade form. No substitutes, facsimiles, or photocopies will be accepted. If you need additional copies, contact your Sales Rep.

You must send back the ORIGINAL AppleShare or LaserShare installer disk. One installer disk is required for each upgrade. For upgrades purchased on or after March 1, 1988, please include your dated original itemized sales invoice. Keep a copy for your records. Products purchased before that date can be upgraded for \$50 each. No orders will be processed until July 1, 1988. After that date, allow six to eight weeks for delivery. If you have questions about the offer, please call (503) 644-4456.

When and Where

The upgrade request must be postmarked before September 30, 1988.

The address for the upgrade is:

AppleShare/AppleShare Print Server Upgrade Program

HyperCard: Variable Space

Revised: 6/24/90
Security: Everyone

HyperCard: Variable Space

=====

This article last reviewed: 17 May 1988

HyperCard 1.1 limits the programmer to 255 global variables. When writing complex stacks, you can run out of variable space. This does not mean you've used your allotted 255 variables. It can mean that the amount of data you've put into the variables exceeds available memory. If you run into this problem, you three things you can do:

First, rethink your use of variables. Can you redesign so that you don't need so many?

Second, you can put empty into a global variable and increase space for other global variables.

Third, if you really need more than 255 global variables, there is a workaround. The following script demonstrates how you can reduce the number of global variables by treat a variable as two-dimensional array:

```
on mouseUp
  global globalVar
  put "Test" into item 32 of line 1000 of globalVar
  put " it worked!!" into item 1 of line 1 of globalVar
  put item 32 of line 1000 of globalVar into item 1 of localVar
  put item 1 of line 1 of globalVar into item 2 of localVar
  put line 1 of localVar into msg
end mouseUp
```

This example, which creates a global variable, "globalVar," having 32,000 elements, shows a more economical handling of variables. Note: A variable can contain only 32,767 characters.

Apple Tape Backup 40SC: Don't Try To Backup Over A Network

=====

This article last reviewed: 18 May 1988

You will probably have a problem if you try to back up data over a TOPS network to an Apple Tape Backup 40SC. The reason is that Apple Tape Backup software is designed for local backup only. In fact, if you try to back up files from a computer other than the one you've connected the backup unit to, the backup software returns an error message that it cannot back up server files.

Other products let you back up over a network. SuperMac Software's Network DiskFit is one product that is designed specifically for backing up AppleShare or TOPS servers and workstations.

LaserWriter: Data Can't Be Stolen From Print Buffers

=====

This article last reviewed: 18 May 1988

Some LaserWriter users -- particularly those with defense work -- have asked if it is possible to extract the contents of the LaserWriter or LaserWriter II print buffer after the page has been printed. The answer is no. Once the information has been downloaded into the printer, there is no way (that we know of) to retrieve it. There is the possibility that by adding hardware to the LaserWriter, data could be captured. But creating and connecting such a piece of equipment would be a very difficult job in itself.

Macintosh-To-Novell NetWare With AppleTalk (Part 1 Of 3)

Revised: 5/10/89
Security: Everyone

Macintosh-To-Novell NetWare With AppleTalk (Part 1 Of 3)

=====

This article last reviewed: 17 May 1988

This is the first of three parts.

Many users have asked about connecting Macintosh to a Novell network, and for up-to-date information on the status of Macintosh NetWare.

The ability of AppleTalk to communicate over broadband networks is done by using:

1. A FastPath (AppleTalk-to-Ethernet converter).
2. A broadband multiplexer (like those sold by Allen-Bradley: VistaMap 10MBps).
3. Another broadband multiplexer to convert the signal back on to Ethernet.
4. A receiving FastPath to convert back onto AppleTalk.

Complete information about NetWare can be obtained by connecting to the Novell demo BBS. The number is (800) 444-4472

Compatibility settings are: 8 bits, parity=none, stops=1, 1200-baud; the access code is NVSOF4.

Here is a brief overview of the Novell information:

With 32 Original Equipment Manufacturers (OEMs) reselling NetWare and with an installed base of over 145,000 file server-based networks, NetWare has become an unofficial standard in the LAN industry.

Netware-Supported Configurations

The following is a list of NetWare-supported networks.

BASEBAND NETWORKS

Linear Bus Networks

Asher-G	AST PCnet II	AST-RSN
AST Starport	AST Turbostar	AT&T StarLAN
Codenoll Ethernet	Cordata InterNet Link	Cordata InterNet Link 286
Corvus Omninet	Gateway G-Net	IBM PC Cluster
IBM PC Network Baseband	MICOM-Interlan Ethernet	NEC Omninet
Network vLAN	Network Elan	North Star Dimension
Novell NetWare Ethernet	Novell NetWare G-Net	Orchid PCnet
Racal-Milgo PLANET	Racore LAN Pac	Santa Clara PCnet/Ethernet
Texas Instruments Ethernet	Torus Ethernet	3Com EtherLink
3Com EtherLink Plus	Ungermann-Bass Net/	Unisys Usernet-86
Univation StarLAN	One Ethernet	Western Digital StarLAN

TOKEN-PASSING NETWORKS

Asher-P	Star Networks:
Comterm ARCNET	
Davong Multilink	TeleVideo Personal Mini
IBM Token-Ring	Novell S-Net
Kaypro ARCNET	
Nestar PLAN 2000	
Novell NetWare RX-Net	
Proteon ProNET-4	
Proteon ProNET-10	
Pure Data ARCNET	
Standard Microsystems ARCnet	
Torus Token-Ring	

BROADBAND NETWORKS

Linear Bus Networks

IBM PC Network
Sytek System 6000
Allen-Bradley Vista

IBM Personal System/2

Advanced NetWare and System Fault Tolerant NetWare provide workstation and file server support for IBM's Personal System/2 series of microcomputer products. Novell also offers a software bridge to link the IBM PC network, the new Token-Ring Network, and other NetWare-supported networks.

Netware Operating System Software

Just as DOS was designed specifically for standalone workstations, NetWare was designed specifically for networking. The NetWare operating system runs

in the file server, which manages shared resources. DOS runs in the workstations, allowing for local processing.

A software component called the NetWare "shell" lets the file server communicate with DOS and application software in the workstations. The shell sends DOS functions to the workstation, but sends NetWare functions to the file server to be handled by the LAN operating system. NetWare remains unchanged, regardless of what software is running in the workstations, which is why NetWare can support many hardware types, and can support multiple versions of DOS on the network simultaneously.

NetWare operating system software offers several powerful features, including DOS 3.x compatibility. DOS compatibility allows multiuser software applications that are developed for DOS to run unmodified on NetWare. Another feature, internal bridging, permits as many as four networks to bridge through the file server.

NetWare is fully compatible with NetBIOS, an industry standard that controls the way software interfaces with IBM and IBM-compatible networks. NetWare's NetBIOS compatibility means that NetWare supports all software and hardware designed around NetBIOS, including software and hardware developed for the IBM PC and Token-Ring networks.

Macintosh-To-Novell NetWare With AppleTalk (Part 2 Of 3)

Revised: 2/1/93
Security: Everyone

Macintosh-To-Novell NetWare With AppleTalk (Part 2 Of 3)

=====

Article Created: 25 May 1988

Article Change History

02/01/93 - REVISED

- To add information about volume limits of 1MB less than 2GB under EXPANDABILITY.

This is the second of three parts.

About The NetWare Operating System

NetWare is the foundation of Novell's product line. It was introduced in 1983, and is now in its seventh generation of development. NetWare offers tremendous connectivity, expandability, and communications capabilities.

NetWare Operating System Software supports 45 popular LAN hardware configurations.

Compatibility

NetWare is compatible with virtually all PC networking software and hardware.

NETWORK HARDWARE

NetWare supports every major network topology and every major manufacturer's hardware (including IBM's PC and Token-Ring networks, AT&T StarLAN, ARCNET, and many Ethernet-type networks). NetWare preserves current hardware investments and lets clients choose the hardware that best suits their price/performance needs. Best of all, the NetWare user interface remains the same regardless of the hardware it is running on.

COEXISTENCE WITH NON-NETWARE PRODUCTS

NetWare can coexist with many non-NetWare products, such as packages developed by IBM for PC-to-mainframe communications. Since both NetWare and non-NetWare products can run on the same network simultaneously, clients are not limited to using only NetWare on a NetWare network. For example, using the TCP/IP Gateway Option, a file server can use both NetWare and TCP environments simultaneously. NetWare also supports important new products being developed by IBM (APPC/LU 6.2 protocols) and other vendors.

CONNECTIVITY

NetWare lets clients interconnect networks through either gateways or bridges. Bridged networks communicate and share information in a way that is transparent to the user. This lets clients purchase networks or add networks, as necessary, without making the original hardware obsolete. Connectivity protects investments in training, software, and hardware.

EXPANDABILITY

NetWare networks can grow easily when the single network limit is reached, clients can simply bridge the network to another network and continue adding workstations and file servers.

It is easy to increase the disk storage and memory capacity of a NetWare network. Disk subsystems may be added to increase hard disk storage capacity to as much as to 2GB. Currently, we have found that a partition size at least 1MB smaller than 2GB seems to work acceptably. Larger volume sizes might cause negative file sizes, inability to copy files because "More space is needed" even though plenty of space is available. You might encounter these symptoms when Novell servers publish volumes larger than 2GB over the network.

Because NetWare can run in protected mode on 286-type file servers, NetWare supports up to 8MB of Random Access Memory (RAM). Additional RAM improves hard disk performance.

DISTRIBUTED PROCESSING

Under NetWare, each workstation is an independent computer performing its own processing. The file server manages the shared resources and coordinates network activity but does not actually process data. This method of managing data is called "distributed processing".

Because each workstation has its own processing power, adding PCs to the network does not decrease the file server's performance. In contrast, terminals connected to mini and mainframe systems share the processing power, which decreases the power available to each user.

OPERATING SYSTEM TECHNIQUES

Reading from and writing to the file server hard disk occurs more

frequently than any other network task. NetWare is specifically designed to perform fast file reads and writes. Other performance enhancements include:

SINGLE-TASKING VERSUS MULTITASKING

NetWare is a multitasking operating system. Performance degradation in the single-tasking environment is magnified with every workstation on the network. Unlike single-tasking operating systems such as DOS, NetWare can service many workstation requests and many hard disks simultaneously.

DIRECTORY HASHING

NetWare minimizes file searching time by efficiently organizing information. Specifically, NetWare indexes directory entries so it can quickly find a file (similar to the way that dictionary entries are alphabetized to enable the user to locate the entry at once).

DIRECTORY CACHING

NetWare saves time by putting a copy of each directory in the file server's RAM. RAM access is much faster than hard disk access, so directory caching significantly increases network performance. Since the disk is accessed less frequently, directory caching also helps eliminate disk-related bottlenecks.

FILE CACHING

NetWare continually tracks parts of files used most often and stores them in RAM. NetWare increases performance by anticipating subsequent requests and reading large blocks of information into RAM. This increases performance by saving "seeks" to the disk, which reduces access time and helps eliminate bottlenecks.

ELEVATOR SEEKING

The disk read-write head travels across the disk and picks up files in its direction of travel, much like an elevator taking floor requests. When a head reaches the end of the disk, it goes in the other direction, picking up new requests. This significantly decreases disk wear and tear and increases disk throughput by up to 50%.

Security

A network supervisor controls network security, which may be implemented on the file server, directory, and file levels. Access to network resources is based on user profiles that the supervisor assigns. Individuals can also protect their personal data without the assistance of a network supervisor.

Value-Added Processes

NetWare offers an elegant solution for developers who would like to place

value-added servers and services on the internet. A common File Service Interface provides for the implementation of value-added processes (VAP) in NetWare servers and bridges. Value-added processes bring new services to Advanced NetWare--namely, specialized servers, the incorporation of third-party devices and specialized technologies. Examples of VAPs are data base servers, communications servers, and print servers.

MHS

Message Handling Service (MHS) is a value-added service that provides message transfer and routing services for LAN-based applications. NetWare MHS moves messages between PC LAN, minicomputer, and mainframe environments throughout a dispersed wide-area network. In the future, MHS will support protocols such as X.25, HDLC, SNA, SDLC, and more.

Macintosh-To-Novell NetWare With AppleTalk (Part 3 of 3)

=====

Article Created: 25 May 1988

Article Change History

02/01/93 - REVISED

- To add note about volume size limitation.

This is the third of three parts.

Connectivity

The purpose of a LAN is to connect users to equipment and information that isn't directly connected to their personal computers. To fulfill this mission, LAN users must be able to talk to more than just devices on their LAN--they must also be able to communicate with other LANs and with other data processing equipment.

Note that a Macintosh accessing a volume larger than 2GB can run into problems. A volume size at least 1MB smaller than 2GB seems to work acceptably. Larger volume sizes might cause negative file sizes, and inability to copy files because "More space is needed" even though plenty of space is available. You might encounter these symptoms when accessing volumes larger than 2GB published on Novell servers over the network.

LAN-TO-NEARBY LAN

Novell offers internetwork bridging to allow multiple nearby LANs to communicate with each other. On a NetWare LAN, the bridge connection in a LAN is transparent--the connected LANs appear like a single network with multiple file servers.

Bridging is accomplished by putting boards from as many as four different LANs in a file server (this is called an internal bridge), or by having up to four LANs share a workstation (external bridging). Either way, the

results are transparent to the user.

LAN-TO-REMOTE LAN

When LANs are too far apart to be bridged locally, other less comprehensive and less convenient connection methods become necessary. There are two basic choices: terminal emulation or remote bridging.

There are many terminal emulation packages available for personal computers that work on LANs. They vary in connection strategies and features offered.

The simplest packages presume you have a local modem board and ask your workstation on the LAN to appear like a VT-100 terminal. The most sophisticated emulators can take advantage of communal modem gateway boards located on the LAN that can serve many users.

High performance, transparent connections are just becoming available for LAN-to-remote LAN bridges. Two of these are Novell's Asynchronous Remote Bridge and Novell's X.25 Remote Bridge.

The asynch version makes a simple point-to-point connection between two LANs. The X.25 link is useful for multipoint connections--where more than two remote LANs are tied together--and for attaching to public data communications networks. X.25 is also useful for attaching to various commercial electronic mail and document-processing systems.

UNA: THE BRIDGE OF THE FUTURE

Novell's Universal NetWare Architecture (UNA) allows a LAN workstation user to access files on many different kinds of computer systems, such as IBM PCs, IBM mainframes, Apples, or DEC's. When the files appear on the screen or are used by an application program, they will always show up in the format of the workstation. A Macintosh user in New York on a UNA LAN, for instance, could look at files on a DEC VAX located in Los Angeles, also on a UNA LAN. The user would see the files displayed as icons just like those used to indicate the Macintosh's own local files. Another UNA user on a PC in Dallas could see the same VAX files by typing DIR on the drive mapped to the VAX.

Conversely, the VAX user in Los Angeles could use the same UNA abilities to explore Macintosh- or PC-originated files, and view them as if they were VMS or UNIX files.

The alternative to UNA is terminal emulation, in which the local workstation acts as a remote terminal on some other computer system. With terminal emulation as the method of connecting, the user must learn and use a new set of commands for each system.

The advantage of UNA is that users and application programs don't have to learn how to use different kinds of machines. The LAN and all the resources on it act like local drives and other local peripherals.

Novell Hardware Solutions

Novell has developed four file servers and two disk drive subsystems for NetWare-supported LANs.

NETWARE FILE SERVERS

NetWare Server 68B

The NetWare Server 68B is specifically designed to be a NetWare file server.

The 68B combines the Motorola MC68000 processor with an S-Net LAN board or an RX-Net LAN board to produce a powerful network "engine."

The 68B supports a combination of four S-Net LAN or RX-Net LAN boards. The NetWare RX-Net LAN board enables the network to support as many as 25 active physical nodes.

Performance is further enhanced by the Parallel/Serial Printer Board (PSPB) which allows parallel and serial ports to be added to the 68B file server. The 68B simultaneously supports as many as five network printers.

NetWare Server 286A

NetWare Servers 286A and T286A are high-performance file servers based on the Intel 80286 16-bit processor.

The 286A offers 1MB of memory on the motherboard, expandable to 8MB with additional boards. The 286A has eight expansion slots, three printer ports, zero-wait-state memory and 6 MHz or 8 MHz clock speed. It supports network LAN boards and other peripherals designed for use with the IBM AT.

NetWare Server 286B

NetWare Servers 286B and T286B are file servers based on the Intel 80286 16-bit processor. The 286B comes with zero-wait-state memory and an 8 MHz clock speed. This file server supports network LAN boards and other peripherals designed for use with the IBM AT.

The 286B offers 2MB of memory on the motherboard, nine expansion slots, and three printer ports. With nine slots, the expansion capabilities of the 286B surpass those of a standard IBM AT and other AT compatibles.

NetWare Server 386A

The NetWare Server 386A comes with 1MB of memory, expandable to 4MB of memory on the motherboard and can support up to 2GB of disk storage with external disk drives. Two 32-bit expansion slots, five 16-bit expansion slots and one 8-bit slot are included in the server.

NETWARE NDS2 AND NDS4

The NetWare Drive Subsystems NDS2 and NDS4 provide additional drive storage capacity for NetWare Servers 68B, 286A, and 286B. The NDS2 and NDS4 provide the following:

- More Network Storage:

The NetWare Server 286A is equipped with a 42MB drive, and the NetWare Server 286B is equipped with a 109MB or 183MB drive. As LAN requirements expand to accommodate more users and more complex application programs, original drives may not provide adequate data storage.

- Disk Mirroring for SFT Level II:

With the SFT NetWare operating system on a NetWare Server 286A or 286B, an NDS2 or NDS4 can provide duplicate network drives.

- Network Drives for 68B-based LANs:

Because the NetWare Server 68B cannot support internal drives, network data storage must be external.

An NDS2 or an NDS4 accommodates a maximum of two or four drives, respectively. Several drive configurations are available.

NETWARE DISK COPROCESSOR BOARD

The NetWare Disk Coprocessor Board (DCB) streamlines the performance of disk reads and writes (disk I/O) for NetWare Servers 286A and 286B, as well as IBM AT file servers.

The DCB controls the drive buffer and provides complete read-after-write verification. The addition of a DCB to a file server improves performance by approximately one-third.

NuBus: Transfer Rate

=====

Article Created: 17 May 1988
Article Last Reviewed: 21 July 1992
Article Last Updated:

TOPIC -----

Some users have asked about the speed of the NuBus data exchange.

DISCUSSION -----

NuBus transfer rate is approximately 2.5MB/sec at 10 MHz.

An average time is 700ns per transaction--"average" because the time is influenced by the type of data being transferred, and by other processes being transmitted across NuBus.

PostScript Language Tutorial and Cookbook: Correction To Manual

Revised: 5/26/88
Security: Everyone

PostScript Language Tutorial and Cookbook: Correction To Manual

=====

This article last reviewed: 18 May 1988

If you are trying to program in PostScript, you may find that THIS program runs perfectly well:

```
/Helvetica findfont
27 scalefont setfont
/rays
{0 1.5 179
{gsave rotate 0 0 moveto 108 0 lineto stroke grestore } for
} def
300 400 translate
.25 setlinewidth
newpath
0 0 moveto
(Pharmaceutical Research) true charpath
stroke
54 -15 translate
rays
showpage
```

Whereas this second program -- which is designed according to the Adobe PostScript programming manual -- does NOT. (The only difference: the word "stroke" was replaced with "clip".)

```
/Helvetica findfont
27 scalefont setfont
/rays
{0 1.5 179
{gsave rotate 0 0 moveto 108 0 lineto stroke grestore } for
} def
300 400 translate
.25 setlinewidth
newpath
0 0 moveto
```

```
(Pharmaceutical Research) true charpath
clip
54 -15 translate
rays
showpage
```

There are two reasons why this second program does not work:

1. The program shown is copied directly from page 103 of the PostScript Language Tutorial and Cookbook (ISBN #0-201-10179-3), except the name "StarLines" is replaced by "Pharmaceutical Research". The output should be the name "Pharmaceutical Research" in outlined letters with the ray pattern inside the letters.

Close examination of the program on page 103 shows that the user left out one critical line. The last five lines in the user's program read:

```
(Pharmaceutical Research) true charpath
clip
54 -15 translate
rays
showpage
```

These lines should read:

```
(Pharmaceutical Research) true charpath
clip
newpath      %-----new line added-----
54 -15 translate
rays
showpage
```

On page 128 of the PostScript Language Reference Manual (ISBN #0-201-10174-2) is a description of the `-clip-` operator, and the last paragraph states:

"Unlike `FILL` and `STROKE`, `CLIP` does not implicitly perform a `NEWPATH` after it has finished using the current path. Any subsequent path construction operators will append to the current path unless `NEWPATH` is executed explicitly. This can be a source of unexpected behavior."

2. On pages 260 and 261 of the PostScript Language Reference Manual, Appendix B (Implementation Limits), there is a list of limits that cannot be exceeded. The `PATH` limit (page 261) indicates the maximum number of points specified in all active path descriptions, including the current path, clip path, and paths saved by `SAVE` and `GSAVE`, cannot exceed 1500.

In this particular case, using the name "Pharmaceutical Research" exceeds the 1500-point limit; thus, the error "limitcheck Offending Command `-clip-`" when using the `clip` operator. If the name is reduced to "Pharmaceutical Rese", the program will execute properly. Adding even one letter to the name will generate the limitcheck error again.

There is a possible workaround for the output wanted. By doing a "gsave" and "grestore" to reset the clip region to its original size, it is possible to make the number of points on the clipping path small enough to avoid the error.

Here is a program that demonstrates one possible solution:

```
/Helvetica findfont
27 scalefont setfont
/rays
{0 1.5 179
{gsave rotate 0 0 moveto 108 0 lineto stroke grestore } for
} def
100 300 translate
.25 setlinewidth
gsave
newpath
0 0 moveto
(Pharmaceutical>true
charpath clip
newpath
100 -15 translate
rays
newpath
grestore
200 0 translate
0 0 moveto
(Research>true
charpath clip
newpath
60 -15 translate
rays
showpage
```

ImageWriter II: Connecting to a VT320 Terminal

Revised: 5/26/88
Security: Everyone

ImageWriter II: Connecting to a VT320 Terminal

=====

This article last reviewed: 20 May 1988

Here's how to connect an ImageWriter II as a slave printer to a DEC VT320 terminal.

Acquire these parts:

DEC cable #BCE16E-xx (MMJ to MMJ) (xx = number of feet)

DEC adapter #H8751-F (MMJ to DB25 male)

Apple Cable M0333 (DIN-8 to DB25 female)

Set up the terminal-to-slave port as a printer port, and set the speed to 9600 baud. You can also select just the scrolling area as the print area, or the whole screen.

Remember to change DIP switch #3 on bank 2 to "off" on the ImageWriter. The printscreen key on the keyboard is the second from the left on the top row (it is usually labelled) and is functional.

Mac286 vs. SoftPC Performance Update: July 1988

Revised: 9/2/88
Security: Everyone

Mac286 vs. SoftPC Performance Update: July 1988

=====

This article last reviewed: 20 July 1988

Here's an update on MS-DOS emulation on the Mac II -- a rerunning of May's benchmark tests. The latest results for the Norton System Information Indexes, DBASE III Plus, and Lotus 1-2-3 version 2.01. are listed below. (All results are in seconds except for the Norton indexes and the accuracy test in 1-2-3.) The old figures for version 1.0 of Mac286 are for comparison purposes.

Monitor setting	Mono	Color	Mono
AST's Mac286	V1.0	V1.01	Insignia's SoftPC
-----	-----	-----	-----
Norton SI Indexes:			

Computing Index:	8.2	8.2	1.2
Disk Index:	3.7	3.7	3.4
Performance Index:	6.7	6.7	1.9
DBase III Plus:			

Launch Program:	7.7	5.8	10.4
Search*:	7.2	4.6	6.7

*: Search 100 record (12 fields) database.

1-2-3 Version 2.01:

Launch Program:	5.6	4.8	10.5
Add Integers:	1.1	1.5	4.0
Add Floating Pt.:	1.1	1.9	5.3
Multiply Integer:	1.3	2.0	4.6
Multiply Floating Pt.:	1.4	2.0	6.2
Integer/SIN:	3.8	4.8	29.0
Load Multiply FP File:	4.0	3.8	10.5

Save Multiply FP File:	3.5	3.2	5.1
Accuracy (SQRT)**:	99.99999936	99.99999936	99.99999936

*: Result of taking the square root of 100 twenty-five times, then squaring that result 25 times. The final result should be 100.

The add, multiply, and integer/SIN tests were done in a 25X25 matrix where the result in each cell was dependent on another cell above or to the left of it.

General Comments:

The hardware setup was as follows: Macintosh II w/2mb RAM, 2-800k floppy drives, 40Mg internal hard disk, 80Mg external hard disk, and a color monitor. All tests with the software were run from the 80Mg external hard disk. The monitor was set to color mode with 256 grey levels for V1.01 tests. This was the only change made from the previous comparison. For version 1.0 of Mac 286 and SoftPC, the monitor was set to mono and 2 grey levels.

A problem in version Mac286 1.01 is that resizing the screen in graphics mode and then returning to text mode causes a 1" margin on the left side of the screen. This is only an annoyance, because you can avoid this problem by moving the horizontal scroll bar to the left and then back to the right edge before returning to text mode. Also, Mac286 sometimes "loses" the cursor when running certain programs (Dollars and Sense, for example).

Utilities for Automatic Periodic Saves

=====

Article Created: 20 May 1988
Article Last Reviewed: 7 July 1992
Article Last Updated: 7 July 1992

TOPIC -----

A user needs a way to save his files automatically and at certain intervals as he works on them. Is there any product which will do this?

DISCUSSION -----

The AutoSave desk accessory from Magic Software automatically saves data from any Macintosh application to the currently logged disk by periodically invoking the Save command from the File menu. The user can set the frequency of saves from 1 minute to 1 hour, as well as stop the automatic save at any time.

NowSave, a module of the Now Utilities package, also works with any application and saves at preset, user defined intervals (either based on time or the number of keystrokes or mouse clicks).

For vendor information, search under: Magic Software and Now Software.

HPGL-To-Macintosh Conversion: A Utility Is Available

=====

This article last reviewed: 24 May 1988

HPGL is Hewlett-Packard's Graphics Language. Hewlett-Packard uses the HPGL commands in their plotters for consistency and ease of interface. The Macintosh can plot to a Hewlett-Packard plotter (HP plotter-driver for the Macintosh) using the HPGL commands. (NOTE: This is strictly for Macintosh applications and Macintosh files for plotting, and has nothing to do with using HPGL files on a Macintosh.)

Stevens Creek Software, Inc. makes a software package -- called MacHP -- that emulates Hewlett-Packard Co. plotters, allowing scientists, engineers, and others to produce plots of scientific data directly on a Macintosh screen.

MacHP allows the Macintosh to emulate the HP7475 and HP7550 plotters. The plotter emulation program converts the Hewlett-Packard Graphics Language (HPGL) commands into screen images on the Macintosh.

Because MacHP plots are object-oriented and use the standard Macintosh PICT format, they can be moved to the Clipboard or saved to a file.

MacHP site licenses are also available. For more information, search under: Stevens Creek Software.

Interfacing Macintosh and Cullinet

Revised: 7/26/89
Security: Everyone

Interfacing Macintosh and Cullinet

=====

This article last reviewed: 7 July 1989

This article describes how to interface Macintosh to Cullinet using InTalk CCL scripts. Note: Palantir Software no longer publishes InTalk. A similar package is FutureSoft's DynamComm. Search the Tech Info Library for "FutureSoft".

It developed from an actual case in which an all-IBM customer was running a package from Cullinet on a 370-type host. The package consists of IDMS-R (database), IDMS-DC (communications monitor), and ICMS. Their PCs communicate with Cullinet using a package called Golden Gate.

Golden Gate is an MS-DOS-based, multi-module application designed to work with IDMS applications. It contains a relational database, spreadsheet, a document processor, and business graphics.

There is no equivalent package to Golden Gate for the Macintosh. However, you can achieve similar results running InTalk with Microsoft Excel or Microsoft Works. Here's how:

Using the CCL script of InTalk, a Macintosh can log on as a TSO user, and issue TSO commands. These commands can extract data from a mainframe file, format the data into a tab-delimited text file, and transfer the formatted file to the Macintosh via the mainframe's PCTrans (or similar Yterm transfer). A script these actions could make the whole process transparent to the user of the Macintosh/InTalk workstation.

Once the tab-delimited text file has been transferred to the Macintosh, a variety of Macintosh applications can open the file. Microsoft Works has most of the functionality of Golden Gate. Omnis 3, Double Helix, 4th Dimension, or other stand-alone database management systems could handle more sophisticated database activities, if needed.

Besides emulating Golden Gate, InTalk CCL scripts can navigate other Cullinet applications via point and click buttons.

MultiFinder allows the InTalk connection to be maintained while working with a Macintosh application.

AutoCad-to-VersaCad Translators Update

Revised: 6/2/88
Security: Everyone

AutoCad-to-VersaCad Translators Update

=====

This article last reviewed: 18 May 1988

People looking for ways to read AutoCAD and/or ComputerVision files into the Macintosh can use VersaCAD and VersaLINK, a file translation program that ships with VersaCAD.

VersaLINK translates at least two types of AutoCAD files into a format VersaCAD can use: Initial Graphics Exchange Specifications (IGES) and Document X-fer File (DXF).

ComputerVision supports the IGES rev 3.0 file format. Therefore, you should be able to translate the files using VersaLINK or other tools, like translators and CAD applications. These are well documented on AppleLink in the Tech Info Library. Search on a combination of IGES, CAD, and AutoCAD.

HyperCard: Problem Printing to ImageWriter II

Revised: 5/2/89
Security: Everyone

HyperCard: Problem Printing to ImageWriter II

=====

This article last reviewed: 25 May 1988

The ImageWriter II has shown a tendency to drop one or two rows of pins (about 1.5" from the top of the page) only when printing from HyperCard. This starts on the second page and continues randomly on other pages. People who experience this also note that other applications print fine.

HyperCard sends a reverse line feed, advances the paper, and tries to resume printing where it stopped. In doing this, it misses two to three pixels consistently, about 1.5" from the top of the page. This anomaly has been reported to the HyperCard Testing group.

Security: Everyone

HyperCard: The Degree of Compacting Depends on Several Factors

=====

Article Created: 25 May 1988
Article Last Reviewed: 9 July 1992
Article Last Updated: 9 July 1992

TOPIC -----

How far can HyperCard compress a stack and how do different elements affect stack and card size (in bytes)?

DISCUSSION -----

Compacting a stack with only one blank card results in no change (5K on disk, regardless of the card size). The amount of compression for a single card (a single blank card requires 64 bytes) depends on the complexity of the graphics, number of fields, and number of buttons. Adding a simple drawing to the card can bring compression to 45% to 50% (depending on the graphics used). However, the addition of a simple button or field can lower that to 40%.

The location of buttons and fields also has an effect. A button or field located on the background creates a smaller size stack. Therefore, the stack shows a smaller percentage of change after compacting because there are fewer objects and less data to be compacted.

HyperCard compression also depends on these factors:

- Graphics -- are they on the card or background?
- Buttons -- are they on the card or background?
- Fields -- are they on the card or background?
- The size of card, button, and field scripts.
- The size of the stack script.

LaserWriter IINT: Printing Speed from IBM PC

Revised: 6/2/88
Security: Everyone

LaserWriter IINT: Printing Speed from IBM PC

=====

This article last reviewed: 24 May 1988

When printing to a LaserWriter IINT from an IBM PC or XT using the Epson LQ2500 emulation, a reasonable speed is 30 to 60 seconds per page. The printing probably would be faster using an AT, 80286, or 80386 system. Some PC-style computers perform better than others.

The LQ2500 emulation mode, under AppleShare PC, translates all Epson commands and text into PostScript commands before sending the job to the LaserWriter. Aside from normal network traffic delays, the speed of the computer doing the translation greatly increases or decreases performance.

A/UX sendmail: How to Resolve Address Path and Rebuild (9/94)

=====

Article Created: 31 May 1988

TOPIC -----

A/UX sendmail: How to Resolve Address Path and Rebuild

DISCUSSION -----

The "/usr/lib/sendmail.cf" file in A/UX is configured with four rules for resolving the address path:

1. For the root@host type of mail syntax, is host in the /usr/lib/uucp/L.sys file?
 - If yes, then path is via "uucp".
 - If no, then path is via "tcp".
2. For the root@host.uucp type of mail syntax, is host in the /usr/lib/uucp/L.sys file?
 - If yes, then path is via "uucp".
 - If no, then path is via "uumail".

(Note that "uumail" is a foreign mailer not yet included in A/UX.)

3. For the root@host.<any domain except uucp> type of mail syntax:

path is via "tcp" (it doesn't matter whether the host is in the /usr/lib/uucp/L.sys or /etc/hosts file).

4. For the host!root type of mail syntax:

path is via "uucp" (it doesn't matter whether the host is in the /usr/lib/uucp/L.sys or /etc/hosts file).

To rebuild a "sendmail.fc" (sendmail frozen configuration file) that might be corrupted or out of date, run the following command:

```
/usr/lib/sendmail -bz
```

Whenever modifying the "sendmail.cf", you should run this command to update the "sendmail.fc" file, because the sendmail daemon reads it to resolve the destination address.

A/UX 1.0: The m_expand returning to 0 Kernel Message (8/93)

Revised: 8/20/93
Security: Everyone

A/UX 1.0: The "m_expand returning to 0" Kernel Message (8/93)

=====

Article Created: 31 May 1988
Article Reviewed/Updated: 20 August 1993

TOPIC -----

This article describes a solution to the "m_expand returning to 0" Kernel message.

DISCUSSION -----

When you encounter the "m_expand returning to 0" kernel message, perform the following command:

```
netstat -m
```

An example of output from this command:

```
56/500 mbufs in use:
    21 mbufs allocated to socket structures
    29 mbufs allocated to protocol control blocks
    4 mbufs allocated to routing table entries
    2 mbufs allocated to interface addresses
0/32 mapped pages in use
157 Kbytes allocated to network (8% in use)
0 requests for memory denied
```

This lets you see how many "mbufs" (memory space) are allocated in your networked system versus the total mbufs allocated. In the example, 500 mbufs are allocated in the system, 56 mbufs are currently used, and 157 Kbytes (256 bytes/mbuf x 500) are allocated to the network. Note the last line: "n requests for memory denied".

If the currently used mbufs are almost equal to or greater than the total allocated mbufs, and/or there are any memory requests denied, you should adjust your kernel parameter on NMBUFS (number of buffers for networking).

Use "kconfig -av" to display the current kernel parameters before modifying them.

Depending on the amount of RAM in your system and network activities, the NMBUFS can be adjusted with the "kconfig" command. For example:

```
# kconfig -n /unix
NMBUFS=1024
<Control-d>
# sync
# sync
# sync
# reboot
```

You also should check these kernel parameters (which may or may not affect your network:

- NBUF (number of system block I/O buffers),
- NINODE (size of system inode table), and
- NFILE (size of system file table pool)

The distributed A/UX 1.0 is configured for a system with 2MB of memory. If you have 5MB RAM installed, you should change the values of NBUF, NINODE, and NFILE to 1000, 200, and 200, respectively. This is mentioned in the A/UX Release Notes 1.0.

A/UX: How to Recover From a Corrupted Toolbox

=====

Article Created: 31 May 1988
Article Last Reviewed: 31 August 1992
Article Last Updated : 31 August 1992

TOPIC -----

What does the following error message indicate?

```
/etc/toolboxdaemon: error opening user interface device: No such device
```

DISCUSSION -----

The error message:

```
/etc/toolboxdaemon: error opening user interface device: No such device
```

may mean that your toolbox user interface device may be corrupted or may have disappeared.

Check to see if the toolbox-specific device `/dev/uinter0` exists. The mode of toolbox-specific device should be:

```
crw-rw-rw-  1 root    sys      4,  0   May 3   16:30  /dev/uinter0
```

If this device file is corrupted or has disappeared, here is how to recover:

1. Bring the system to the single-user mode.
2. In single-user mode, type the command

```
# /etc/newunix toolbox
```
3. Type the command

```
# /etc/autoconfig -u -v -o /unix -S /etc/startup
```
4. Type the commands:

```
# sync  
# sync  
# sync
```

7. Reboot with the command
reboot

This should not happen in A/UX 2.0 and beyond.

TI 2108 Printer Can Be Used With Macintosh

=====

This article last reviewed: 26 May 1988

The Texas Instruments Model 2108 printer can be used with the Macintosh.
Here are some of its features:

- LocalTalk connection
- based on the Ricoh laser engine
- contains 2M of RAM for imaging
- prints at 8 pages-per-minute (8ppm)
- 13 resident fonts
- slots for font cartridges (also accepts downloadable fonts)
- Centronics/IBM parallel connector
- RS-232 serial connector
- RS-422 connector
- resolution: 300 dots-per-inch
- page description language is PostScript
- emulates:
 - Diablo 630
 - Epson dot matrix family

LaserWriter IINT and IINTX: How Its 2MB RAM Is Allocated

=====

Article Created: 26 May 1988
Article Last Reviewed: 7 April 1992
Article Last Updated: 7 April 1992

TOPIC -----

How is the RAM allocated on the LaserWriter II series of printers?

DISCUSSION -----

The 2MB of installed RAM is allocated approximately like this:

- 1MB is reserved for the frame buffer. This is where the page is assembled from the PostScript descriptions sent by the computer.
- 200K is reserved for font caching, display list, and the AppleTalk communications buffer. This is where font bitmaps are stored to speed the font access when used again. It is also where the display list is generated by the downloaded PostScript before it is sent to the frame buffer for actual page description.
- 300K is reserved for the PostScript interpreter as well as the server and user dictionaries.
- This leaves about 500K of virtual memory (VM) for fonts, prep files, and program memory. Tech Comm checked the VM with the "vmstatus" operator within PostScript and found that 511,316 bytes were available on a freshly-reset LaserWriter IINT with 2MB of memory. Of that amount, 81,850 bytes were used (possibly for the PostScript interpreter), which leaves about 429K.

LaserWriter II: Why Its Image Area Is Limited

Revised: 6/2/88
Security: Everyone

LaserWriter II: Why Its Image Area Is Limited

=====

This article last reviewed: 26 May 1988

Users have asked whether the LaserWriter II, with its support for large RAM, can print a complete legal size page instead of the 6.72-inch by 12.84-inch area formerly available per page?

The LaserWriter drivers and most current applications were written before Apple introduced the LaserWriter II with increased memory. When this software was written, there were memory constraints in the LaserWriter that had to be worked around.

Although these memory constraints are going away, the application still assumes the same printer memory limitations. Other limitations were/are added by the driver.

Many applications have large margins, differing in size but larger than the LaserWriter requires.

IBM 3151 Terminal: How to Connect to a Macintosh

=====

This article last reviewed: 1 June 1988

The IBM 3151 is IBM's configurable ASCII terminal -- in its "vanilla" mode, it's just an ASCII "dumb" terminal. It can accept "personality" modules that allow it to appear as a DEC VT100 or IBM 3101-compatible terminal.

To connect: hook up the Macintosh. Use a communications application such as MacTerminal to capture the text to a disk file for later manipulation.

AppleLine: Version 3.35 ROMs Correct Missing 25th Line

=====

This article last reviewed: 2 June 1988

Some AppleLine users have reported that, in MacTerminal, they can't access the 25th line on the mainframe screen.

The recent ROM revision (version 3.35), which added 3174 support to the AppleLine, is supposed to automatically bring the AppleLine up in the mode that displays the 25th line. The old ROMs did not do this: before this upgrade, the terminal type had to be set to MacTerminal in the AppleLine Supervisor to display the 25th line.

When AppleLines display the 25th line, either:

- they have the newer ROMs, or
- the AppleLine Supervisor has been set up to display it.

In either case, all AppleLines should have the newest ROMs installed to ensure compatibility with other possible configurations.

Macintosh Internal Hard Drives: Vibration Testing

=====

This article last reviewed: 2 June 1988

The shock limit for the Macintosh SE's internal hard disk drive is defined as 40G -- for an inactive drive.

Apple tests the drive (only) to these limits:

Macintosh SE

.25G, 3 to 300 Hz in the vertical direction (Z-Axis) only. Testing frequency is held for 15 minutes at drive resonance as determined by attached accelerometers.

Macintosh II

.25G, 3 to 300 Hz in all three directions (X-axis, Y-axis, Z-Axis).

Airplane frequencies are at the higher end of the tested frequency spectrum and could easily exceed those frequencies at higher amplitudes.

AppleShare: Date Problems May Be due to Mixed Versions

=====

This article last reviewed: 2 June 1988

If you encounter problems with dates on an AppleShare server -- for example, one user reported seeing, from a workstation, file modification dates that were 40 years off -- be sure your workstations are all running the same version of AppleShare software that the server is running.

The way AppleShare 1.1 sends dates over the network is different from the way version 1.0 did it. Mixing the two versions on one network can result in erroneous dates.

LocalTalk Over IBM Cabling (10/96)

Revised: 10/1/96
Security: Everyone

LocalTalk Over IBM Cabling (10/96)

=====

Article Created: 1 June 1988
Article Reviewed/Updated: 1 October 1996

TOPIC -----

This article describes using LocalTalk over IBM cabling.

DISCUSSION -----

You can run LocalTalk over the IBM Cabling System. If your customer has installed the IBM Cabling System, there are several cabling types and all of them can be used to construct an LocalTalk network using PhoneNET Connectors and the PhoneNET StarController.

- Type 1 Data Cable has two individually shielded twisted pairs of 22 gauge solid copper wire.
- Type 1 Outdoor Data Cable is Type 1 Data Cable with a corrugated metallic shield.
- Type 1 Plenum Data Cable is Type 1 Data Cable with plenum rated plastic (most plenum cable uses teflon)
- Type 2 Data & Telephone Cable has Type 1 Data Cable and four pairs of unshielded solid copper 22 gauge wire.
- Type 2 Data & Telephone Plenum Cable is Type 2 Data & Telephone with plenum rated plastic
- Type 5 Fiber Optics Cable has two optical fibers.
- Type 6 Data Cable is the same as Type 1 Data Cable, except that the wire size is 26 gauge.

The IBM Cabling System uses three types of cable ends. All the cable ends are color-coded, making it easy to put the right wires to the right posts.

- The Data Connector is a unisex connector system with four conductors. It does everything. Two of them will mate together, so there is no male or female version.
- The Three-Pair Modular Telephone Jack Connector is a RJ12 (six pins) with barrel connection posts on the back.
- The Four-Pair Telephone Jack Connector is a RJ45 (eight pins) with barrel connection posts on the back.

All wires go from a face plate back to a distribution panel in the wiring room. The face plate can either have just a data connector or it can have a data connector and a three-pair telephone Jack. The distribution panel mounts in a standard 19-inch rack. The maximum wire length from an office to the distribution panel is always much less than the distance limitations of a PhoneNET wiring scheme.

The preferred method of attaching to the IBM Cabling System is to use the fourth telephone wire pair in the Type 2 Data Cable. Wire a normal RJ11 wall jack next to the fancy IBM data connector face plate and attach the spare pair to pins 2 and 5 (yellow and black) on the RJ11. (This is the preferred wiring method, but in some places that have the IBM Cabling System the telephone people typically won't let the data communication people touch anything that looks like telephone cabling and most certainly not their new IBM Cabling. Of course, if you have only Type 1 Cabling, then you have no telephone cabling and you have to go to plan B.

The alternate plan is to use a special expensive adapter so that the data cables can be used. Farallon sells a special Data Connector that has an RJ11 female socket on it. Farallon Part Number: TE300, IBM Cabling System Line Tap. Two are required for each office to go onto the network, one in the office to provide a place for the modular cable from the PhoneNET to attach into and one at the Distribution Panel. If the network is just four offices on the same floor, you can rig a Passive Star PhoneNET network.

More common is to install a PhoneNET StarController on each floor and to buy the special 19-inch rack-mount StarController Wiring Kit TE347. Normal telephone modular cable can be connected from the TE300 into the RJ11s on the StarController Patch Panel.

This information provided by Farallon Computing.

HSV-To-RGB Mapping and Color Models (Part 1 Of 2)

Revised: 7/2/92
Security: Everyone

HSV-To-RGB Mapping and Color Models (Part 1 Of 2)

=====

Article Created: 24 May 1988
Article Last Reviewed: 30 June 1992
Article Last Updated:

TOPIC -----

This is the first of a two-part article on HSV-to-RGB mapping and color models.

DISCUSSION -----

There are several color models for color monitors. The most common are:

- HSV
- HSL (synonymous with HIS)
- CMY
- RGB
- YIQ

(NOTE: The Color Picker Package defines parameter values from 0 to 65535 for each of these models.)

The Macintosh II Color Picker Package uses the RGB, CMY, HSV, and HSL models. Each of them is described below.

The RGB and CMY Models (Red-Green-Blue and Cyan-Magenta-Yellow)

The RGB model defines its colors as mixtures of the additive primary colors: red, green, and blue. The RGB model organizes colors into a three-dimensional cube. Differing values of red, green, and blue define the model. (The human eye can see all visible colors in combinations of three base colors.)

The CMY model features cyan, magenta, and yellow values. These are the

subtractive (or complementary) primary colors. The model works in the same manner as the RGB model--that is, a three-dimensional cube is fashioned with the three color values.

The association between RGB and CMY is one-to-one: cyan is the complement of red, magenta the complement of green, and yellow the complement of blue. A color defined in values for red, green, and blue in the RGB model is defined in values of cyan, magenta, and yellow in the CMY model. For conversion purposes, each of these two models is the other's complement.

For example, given a maximum value of 65535 and a minimum value of 0, a pure red color in the RGB model containing 65535 red, 0 green, and 0 blue has a CMY color of 0 cyan, 65535 magenta, and 65535 yellow.

The HSV Model (Hue-Saturation-Value)

The HSV model appears as a color cone. The three parameters describing this cone are hue, saturation, and value.

"Hue" describes the primary attributes of a color. A color hue for purple has both red and blue primary attributes or hues. A given purple may contain more blue than red; therefore, the hue of that particular purple is blue.

"Saturation" is a value measuring the amount of mixing between primary colors like red, green, and blue. A fully-saturated red contains only the color red and has no other primary color attributes; that is, no mixtures of blue or green. Colors that are slightly or minimally saturated contain mixtures of the primary colors and might contain red, green, and blue. A color that has no saturation at all is white. In the HSV model, the primary colors appear along the edges. They mix together toward the center, growing lighter in hue and becoming less saturated as they near the center. The center is white, and contains equal amounts of all the colors.

"Value" describes the brightness of a color. A red can be made brighter or darker by adjusting its value. A white in the center of the HSV model becomes darker, grows to gray, and finally becomes black if followed along the center of HSV model to its point.

The HSV model is a single-cone shape based on the coordinate values of hue, saturation, and value. Colors are mixed within the cone and appear as primaries along the edges, spaced every 60 degrees. For example, starting with the color green on the perimeter, the colors following are yellow, red, magenta, blue, cyan, and back to green (or the reverse, depending on direction around the cone). The color white is anywhere on the center line of the cone where all of the colors are mixed evenly and the value or brightness is at a high level.

In the HSV model, the apex describes the lowest intensity level, and the base describes the highest intensity level of a color. Points within the cone are colors made up of mixtures of hue and saturation. A color's intensity is the point's distance above the base.

Visualize a cone with a hexagon just fitting the mouth of the cone. In this cone, these edges represent the primary colors. The center of the hexagon is a white wire with one end at the tip of the cone. The wire, while white at the wide end or base, grows more gray as it recedes to the tip, where it at last becomes black.

The HSL (Hue-Saturation-Luminance)

The HSL (or HIS, hue-intensity-saturation) model is a double cone with the bases connected. It follows the same parameters as the HSV model, but the colors filling the base and sides have values rising and falling to each apex of the cones. The apexes are defined as the brightest color point (white) and the lowest color point (black)--similar to the HSV model, where the apex gradually darkens, and all colors fade to black. However, in HSL the colors fade to black AND white. The colors rise in value, becoming brighter, but are also brought closer together by the angle of cone's surface toward the white center. This model is used in Tektronix display devices.

"Intensity" and "luminance" both define the strength or brightness of a color. This is like the "value" parameter of the HSV model, but is defined with the brightest primary color values occurring in the center of the model rather than at one end. The colors could become brighter near the white point, but lose their identity when they mix with other colors as they approach the white apex.

To model HSL/HIS, two cones are connected to make a hollow shape with the hexagon sandwiched inside. The lines extending from the points on the hexagons connect to the points on both cones.

This article is continued in "HSV-To-RGB Mapping and Color Models, Part 2 Of 2."

HSV-To-RGB Mapping and Color Models (Part 2 Of 2)

=====

Article Created: 24 May 1988
Article Last Reviewed: 30 June 1992
Article Last Updated:

TOPIC -----

This is the second of a two-part article on HSV-to-RGB mapping and color models.

DISCUSSION -----

Converting from RGB to HSV or HIS

When converting HSV to RGB, the HSV model always has at least one RGB value equalling the intensity or value of the HSV model color.

When converting HSV to RGB, the HSV model sets the value parameter to the largest RGB value.

When converting RGB to HSL/HIS, the HSL model always sets the luminance or intensity parameter to equal the midrange of the RGB values.

The hue values for the HSV model always equal the hue values from the HSL model.

References

"Raster Graphics Handbook" Conrac Division, Conrac Corporation Van Nostrand Reinhold Company Inc. 135 West 50th Street New York, New York 10020

"Fundamentals of Interactive Computer Graphics" James D. Foley, Andries Van Dam, Addison-Wesley Publishing Company Menlo Park, CA

For the HSL model (also called HIS), both books use "Status Report of the Graphics Standards Committee," Computer Graphics volume 13, number 3, Association for Computing Machinery, New York, August, 1979.

The HSL model provided in both books is based on the SIGGRAPH article. There is a typographical error in the calculation for converting from RGB to HSL. This error appears in the article and is replicated in the books.

The correct calculation for color saturation from red, green, and blue values is:

```
If luminance <=.5 then
    saturation := (max - min) / (max + min)
else
    saturation := (max-min) / (2 - min - max)
```

Apple Computer uses the corrected calculation in its Color Picker Package.

MacSchool Now Incorporates NCS 3000 Grade Scanner

=====

This article last reviewed: 24 May 1988

Some of our education-industry users have asked if there is a driver for the NCS 3000 test grade scanner.

For those users in search of a complete educational-administration solution, Chancery Software has just incorporated the NCS 3000 into MacSchool. MacSchool can now read cards for daily attendance confirmation, do grade reporting for grade card preparation, and handle student course request and registration.

Cabling

If the MacSchool system is installed, the cable between the NCS 3000 and the Macintosh is already in place. If the school only wants to grade tests (without installing MacSchool), they need to make the cable. Since the NCS 3000 uses a serial interface to communicate with a computer, a hardware technician should have no trouble making the cable.

Software

4th Dimension is designed to collect data from the serial port and store the collected data for further processing. Its scripting language contains functions for reading the serial port. If HyperCard will be used, there are XCMDs in the public domain for reading serial ports. In both cases, software must be written to address the specifics of scoring tests.

LaserWriter IISC: Compared to H-P DeskJet

Revised: 6/2/88
Security: Everyone

LaserWriter IISC: Compared to H-P DeskJet

=====

This article last reviewed: 24 May 1988

Here are the functional differences between the Hewlett-Packard DeskJet and the Apple LaserWriter SC.

The HP DeskJet has two draft modes: 300x150 dpi and letter quality (300x300 dpi).

It is rated at two pages-per-minute (2ppm), compared to the LaserWriter SC at eight pages-per-minute (8ppm). The DeskJet pauses between pages to allow the ink to dry.

The DeskJet is designed for lower volumes (40 to 50 pages-per-day), while the LaserWriter SC can work at 150+ pages per day.

The DeskJet comes with one typeface family of nine fonts (Courier, Courier Bold, and Courier Compressed at 10, 16.67, and 20 characters-per-inch -- all at the same point size).

The LaserWriter SC comes with four typeface families (Courier, Times, Helvetica, and Symbol) each with bold, italic, underline, outline, subscript/superscript, and (with some applications) small caps each in 9-, 10-, 12-, 14-, 18-, and 24-point sizes -- approximately 1,000 fonts altogether.

The DeskJet fonts must be selected from the front panel, so font mixing is limited. The LaserWriter SC is able to deal with a wide variety of fonts, and the changes are made on the screen in the traditional Macintosh method.

The DeskJet ink cartridges must be changed every 500 to 800 sheets and cost approximately \$20 each. DeskJet cartridges cost about \$20 per 3000 sheets more than LaserWriter toner cartridges.

A/UX: Making an A/UX System Run as a Sun/NFS Client (8/94)

Revised: 8/24/94
Security: Everyone

A/UX: Making an A/UX System Run as a Sun/NFS Client (8/94)

Article Created: 29 June 1988
Article Reviewed/Updated: 23 August 1994

TOPIC -----

Making an A/UX System run as a Sun/NFS Client.

DISCUSSION -----

To get your A/UX system running as an NFS client, follow these steps:

1. You must have already set up bnet (basic network). bnet is a prerequisite for running NFS. The command is: `newconfig bnet nfs`. For details, see "Configuring and Managing a TCP/IP Network" in the A/UX Network System Administration manual.
2. Make sure a set of network daemons -- `"/etc/inetd"` -- is installed and running from the `/etc/inittab` file. The daemon in the `/etc/inittab` entry should state:

```
net9:2:respawn:/etc/inetd      # set to "respawn" for networking
```

The `nfs` kernel module is also required and is included if you run the `newconfig bnet nfs` command described above.

3. The `"/etc/biod 4"` and `"/etc/mount -at nfs >/dev/syscon 2>&1"` daemons must be installed and running from the `/etc/inittab` file. Here are the two daemons in the `/etc/inittab` entries:

```
nfs4:2:wait:/etc/biod 4      # set to "wait" for NFS client
nfs8:2:once:/etc/mount -at nfs > /dev/syscon 2>&1 # set to "once" for NFS
```

For more detail, see "Configuring and Managing the Network File System" in the A/UX Network System Administration manual.

4. After you have completed these steps, use `"ps -ef"` to verify that the

above processes are running.

5. Use "showmount -e remote_nfs_server" to see which filesystems of remote_nfs_server machine have been exported to you.
6. Issue the "mount" command for the exported filesystem(s). If either the "showmount" or "mount" command fails, chances are that the remote NFS server might not be up or the permissions are not granted for you to mount the remote server.

A/UX: How to Check for Files without Changing Them (8/94)

Revised: 8/25/94
Security: Everyone

A/UX: How to Check for Files without Changing Them (8/94)

=====

Article Created: 1 June 1988
Article Reviewed/Updated: 24 August 1994

TOPIC -----

In attempting to check for the presence of a file without correcting any errors, an A/UX user tried the following command from the SASH (Stand Alone Shell) application's command line:

```
esch -v -b -f
```

This command automatically corrected a permissions error on a file.

(Editor's Note: SASH is equivalent to the A/UX 3.0 Startup shell.)

DISCUSSION -----

The reason is that "escher" begins the autorecovery process. It does generate a report when it discovers a file that does not match the rules in the CML (Configuration Master List). It also updates the CML but it will not tell you what was updated.

For instance, "escher" does not distinguish between changed permissions and changed contents. It only asks if you want to update the autorecovery file system with each changed file. It also does not create checksums for files. For this reason, use of escher is discouraged.

The "-m" option would probably be better if you do not wish to answer all the questions. This option merely mails a list of updated and missing files.

Refer to the A/UX Local System Administration manual section on "Managing Disks" for details about the use of autorecovery.

How do I enter character sequences like Control-V, Control-Q, and Control-S into a file?

DISCUSSION -----

vi(1) doesn't disable xon/xoff mode when it sees a Control-V, nor does it let you type Control-S or Control-Q into a file. The reason is that Control-S and Control-Q are special characters for controlling output flow.

If you precede your "vi" with "stty -ixon", flow control will be disabled, allowing generation of these characters within your file.

"stty ixon" is the default on login.

A/UX: Booting from the "A/UX Standalone Shell" Floppy

=====

Article Created: 1 June 1988

Article Change History

08/31/92 - REVIEWED

- For technical accuracy.

TOPIC -----

In theory, A/UX can run from a hard disk having only two partitions, root/usr and a swap. (Tech Comm does not recommend this, as repartitioning is not an easy task.) Because A/UX boots from the SASH program within the Macintosh Operating System, use the boot floppy labeled "A/UX Standalone Shell". It contains the SASH application and utilities and the System file (but not the Finder).

DISCUSSION -----

Here is how to boot A/UX from the floppy:

1. To open the SASH application, insert the floppy "A/UX Standalone Shell" and click Cancel.
2. Within the General Preferences menu item, set the root directory to the hard disk address of the kernel you want to launch.
3. Type "launch" on the SASH command line and press [Return].

EtherTalk: How It Handles Multiple Protocols (6/93)

Article Created: 6 June 1988
Article Reviewed/Updated: 25 June 1993

TOPIC -----

This article describes how EtherTalk handles multiple protocols.

DISCUSSION -----

The EtherTalk card is a low-level transport mechanism which can move a variety of protocols over an Ethernet network. "Low-level" means that the EtherTalk card only addresses itself to the lower two layers of the ISO reference model -- the physical layer and the data-link layer. The upper layers of the session are controlled by whatever protocol you implement over these two lower layers. Two examples of upper layer implementations are AppleTalk and TCP/IP.

The card, using the software driver, places these upper-layer protocol packets (either AppleTalk packets or TCP/IP packets) in the data field of the Ethernet transport frame. The Ethernet frame properly addresses these packets to their "target" devices. The target device strips off the frame and then processes the packet contained inside. On the Ethernet wire, a device doesn't care about what a frame contains, unless that frame is directed at that device.

Therefore, you can use different, upper-layer protocols -- like TCP/IP, XNS, or AppleTalk (among others) -- on the same physical wire. These encapsulated packets can co-exist on a single Ethernet without interference, because a device does not look at what's inside the packet, unless it's addressed to that device.

The software shipped with EtherTalk is a driver for the Macintosh II that redirects AppleTalk packets to the EtherTalk card rather than to the printer port. The EtherTalk card then encapsulates the AppleTalk packet in an Ethernet frame for delivery to a device on Ethernet that understands AppleTalk packets.

For example, picture two Macintosh II computers connected directly to Ethernet. One runs AppleShare and acts as an EtherTalk server. The second acts as an EtherTalk workstation. Both of these devices use Ethernet only as a physical connection with delivery assurance and error correction capabilities.

An example of what the EtherTalk card can do is encapsulate TCP/IP under A/UX. Here, an Ethernet frame is again used, but the packet contained inside the frame is TCP/IP, rather than AppleTalk. You can also use other protocols, like XNS, with the same card, using the same Ethernet frame. The only thing that changes is the frame contents.

With Ethernet, you can also have one device "push" more than one protocol over the same physical connection. An example is a VAX running VMS with AlisaTalk and DECnet installed. AlisaTalk delivers AppleTalk packets to the VAX that encapsulates them in an Ethernet frame and sends them out onto the Ethernet network. The VAX can also "push" DECnet packets encapsulated in the Ethernet frame over the same card and physical connection.

All this happens serially (rather than in parallel), because Ethernet is a baseband network. In our example, the AppleTalk packet goes out first, followed by the DECnet packet over the same wire, obeying the rules of Carrier Sense Multiple Access/Collision Detect (CSMA/CD). Again, Ethernet provides the delivery assurance and error correction.

The table below shows the software deliverables associated with the EtherTalk card available from Apple:

Operating System	Upper Layer Protocol	How Delivered
-----	-----	-----
Macintosh OS	AppleTalk	EtherTalk
A/UX	TCP/IP	A/UX

•For technical accuracy

TOPIC -----

What is the relationship between A/UX and the Macintosh operating system?

DISCUSSION -----

A/UX and the Macintosh operating system are two distinct entities. The user boots the Macintosh II either into the Macintosh OS or into A/UX. One operating system is not a window or shell in another. Each stands alone.

A/UX includes Macintosh ToolBox support. Thus, an A/UX application might LOOK like a Macintosh application, with windows, menus, and so on. In fact, a "well-behaved" Macintosh application can be ported to A/UX and run under UNIX using the same toolbox calls it did under the Macintosh operating system.

A/UX: The "rwhod" Daemon Increases Network Traffic (9/94)

=====

Article Created: 8 June 1988
Article Reviewed/Updated: 19 September 1994

TOPIC -----

The "rwhod" daemon ("in.rwhod" in A/UX) maintains the database used by the "rwho" and "ruptime" programs.

DISCUSSION -----

Doing this causes a lot of network traffic. Approximately every 60 seconds the daemon broadcasts and queries the state of each system (host) on the network. This action is network intensive (meaning the network response time becomes slower) on an already user-loaded network.

Suggestion: If you have a heavily loaded network and system performance is a concern, turn off the "in.rwhod" daemon. Note: The output of "rwho" and "ruptime" commands is meaningless if "in.rwhod" is not running.

HyperCard 1.2 and Mediagenic Reports: Problem and Workaround

=====

This article last reviewed: 17 June 1988

When you upgrade from HyperCard 1.1 to HyperCard 1.2, Reports by Mediagenic (formerly Activision) may not work correctly.

Here's the problem. In the background script of the report card are these lines in the InvokeReports handler:

```
- on InvokeReports docName:

    if the version is "1.0", then
        if MultiFinder(), then
            ...
    else if the version is "1.1", then
```

Here's the workaround: change the last line to read:

```
    else if the version >= "1.1", then
```

Macintosh II, IIfx & IIfx: Power Up Questions And Answers

=====

Article Created: 10 November 1988
Article Last Reviewed/Updated: 29 November 1995

TOPIC -----

This article covers several questions about powering up a Macintosh II, Macintosh IIfx, and Macintosh IIfx.

DISCUSSION -----

Question: Is there a way to power up the Macintosh when AC power is supplied, instead of toggling the keyboard button or the power button on the back of the Macintosh II?

Answer: There is a way to power up the Macintosh without pressing a button. However, this requires modifying the power supply or using a power supply other than the one supplied.

Circuitry in the Macintosh II, IIfx and IIfx power supply senses a level transition from the logic board, which is initiated by pressing either the button on the back of the machine or the Power On key on the ADB keyboard. The power supply must sense the transition to being the power-up cycle. If this transition does not occur, the power-up sequence does not start. Therefore, if the power supply is modified to provide (or another power supply is used that provides) a steady voltage to the power fail signal line of the power supply, the power-up sequence does not start.

Question: How does the power button on the back of the Macintosh work? Does it short pins 2 and 4 on the ADB port, or does it do something else?

Answer: Pin 2 of the ADB port is the power on (PwrOn) signal line; pin 4 is ground (Gnd). When the reset key is pressed, pin 4 (Gnd) is connected to pin 2 (PwrOn) through a 1N914 diode. This supplies Gnd to the input of a CMOS chip on the logic board, which turns on a transistor and applies approximately +6VDC to the power fail warning (PFW) signal line. This level shift on the PFW signal

line initiates the power-up sequence in the power supply. Once the power supply is powered up, +5VDC is applied through a diode to the same line, which keeps the power supply powered up.

Question: Can the power button on the back of the Macintosh be replaced with a power-sensing switch?

Answer: When replacing the switch on the back of the Macintosh:

- Ensure that all connections are correct (the switch is a double-pole, double-throw type).
- Ensure that the new switch performs the same functions as the original switch (that is, it switches ground in to the shut-down circuit to shut off the system, and it switches power in to the circuit to turn on the system).

Question: Can the logic in the power supply be bypassed so that it does not sense anything from the motherboard?

Answer: It may be possible to bypass the power fail logic in the power supply; however, it is probably easier to replace the power supply with one having the same functions, but that handles power fail differently. A power fail-type circuit is necessary because there is a thermal sensor on the Macintosh II logic board that shuts down the system if high temperature is detected. This same circuit also shuts off the power supply in response to the Shut Down menu command.

Another possible solution is to create a circuit that plugs into the ADB port, which generates pulses between 3.0VDC and 6.8VDC for >1.5 seconds on pins 2 and 4. This would trigger the power fail circuit in the present power supply to power it up.

The logic in the power supply also generates a PFW signal to the system when there is an AC input voltage failure. If AC power is removed, the power fail circuit pulls PFW low at least 2 ms before the DC power fails.

For further information on operational restrictions, see the "Designing Cards and Drivers for the Macintosh II and Macintosh SE" manual (Addison-Wesley, ISBN 0-201-19256-X), chapter 6, page 4.

All of these factors should be taken into consideration before removing the existing power supply.

Macintosh System Software 6.0 Changes (part 1 of 4)

Revised: 5/10/89
Security: Everyone

Macintosh System Software 6.0 Changes (part 1 of 4)

=====

This article last reviewed: 15 June 1988

Introduction

This article is an overview of the most notable changes made to the Macintosh System Software since the 5.0 release. For more detailed information, see parts 2 through 4.

QuickerGraf

Color QuickDraw now incorporates Andy Hertzfeld's QuickerGraf. Previous public domain versions of QuickerGraf were made available in the form of INIT and CDEV files, but in System Software 6.0, it's in the System file. Users should throw away QuickerGraf INIT or CDEV files when upgrading to System Software 6.0.

Pop-Up Menus

Pop-Up menus work on multiple Macintosh II monitors when running under MultiFinder.

Version Information

The Get Info window now has a field for reporting the file's version. For files, such as documents, that have no version information, the value "Not Available" appears.

Disk Copies

When copying an entire floppy disk to another, the Finder now uses an image copy to create an exact duplicate of the original disk.

MultiFinder

Double-clicking on a document, when the application is already open, now

activates the application and then opens the document.

Printer Tools

Five printer drivers are included with System Software 6.0:

- ImageWriter
- AppleTalk ImageWriter
- LaserWriter IISC
- LaserWriter IINT
- LaserWriter IINTX

The LaserWriter Drivers now support 11" x 17" paper. A new radio button in the Page Setup dialog box makes this new size available.

There is a new check box in the Page Setup dialog, and another has been modified. The Text Smoothing option smooths bit-map fonts that are downloaded, and the Graphics Smoothing option smooths bit maps other than text. Because of this new feature, this version is incompatible with all previous versions of LaserWriter Prep.

HD SC Setup

HD SC Setup now lets users divide a Hard Disk into multiple partitions. This is particularly useful to A/UX users.

Installer Scripts

Mini-Scripts for the Installer are included. They create a system that is configured only for the type of Macintosh that it was created for. Patches for the other Macintosh types are not installed with Mini-Scripts. Starting up a system configured for one Macintosh type on a different Macintosh type will cause an alert box indicating that the system was intended for a different Macintosh configuration.

CloseView

The new CloseView utility lets users magnify the screen image. This is particularly useful to visually impaired users. Because CloseView is a CDEV, it's accessed via the Control Panel.

Map

The new Map CDEV records and displays the longitude, latitude, and time of locations anywhere in the world.

Macro Maker

The new Macro Maker utility lets users to create macros that automate repetitive tasks. Macro Maker is an INIT that's made available through an icon that appears in the menu bar.

Macintosh System Software 6.0 Changes (part 2 of 4)

Revised: 5/10/89
Security: Everyone

Macintosh System Software 6.0 Changes (part 2 of 4)

=====

This article last reviewed: 15 June 1988

Macintosh System Software 6.0 includes four disks:

- System Tools
- Printer Tools
- Macintosh Utilities 1
- Macintosh Utilities 2

The contents of these four disks are described in the three articles
"Macintosh System Software 6.0 Changes" (parts 2 through 4).

SYSTEM TOOLS DISK

System File

Color Picker Package

When using 8-bit mode on a device with a CLUT, Color Picker now displays
36 slices in the color wheel rather than six.

Known Color Picker Bugs

- Gray scale fonts can look blotchy with ColorPicker in 16-color mode,
because the grays used in the font can be changed while the package is
running.
- The ColorPicker uses a fair amount of memory, and its error checking for
out of memory conditions is lax. If you call GetColor in low memory
situations, you are likely to run into a system error.
- GetColor assumes that the color environment is stable when it is installed.
If you have used Palette Manager or Color Manager to change the color
environment, GetColor often initially selects the wrong color. Almost
any user action will cause ColorPicker to refresh the colors, and

therefore correct this situation.

Color QuickDraw

Color QuickDraw now incorporates Andy Hertzfeld's QuickerGraf. Previously, the color used as the transparent color (for arithmetic transfer mode #36) was the port's RGBBkColor. Now, in CGrafPorts only, the transparent color is specified by the port's rgbOpColor -- transparent mode drawing in old GrafPorts will continue to use bkColor to determine the index of the transparent color.

Menu Manager

Pop-Up menus work on multiple Macintosh II monitors when running MultiFinder.

Notification Manager

The Notification Manager allows a process, such as an application, desk accessory, or device driver to asynchronously alert the user that it wants or needs attention.

Operating System Utilities

A fix has been made to the System file to correct a long-standing problem in UpString, which selectively uppercases and de-diacriticalizes strings for operating system use. Strings that included the accent grave (\$60), when passed to UpString, returned a lower case 'a' instead of leaving the accent unchanged.

Palette Manager

A bug has been fixed that caused a crash if more than 16 palettes were used.

The problem that resulted when calling PmBackColor with a palette entry whose usage was pmExplicit has been fixed.

When a palette is activated, all gDevice CLUT entries are unprotected on all devices affected by the palette.

pmTolerant entries, other than black and white, can now occupy position zero in a palette.

A bug relating to color table animation and changing depths has been fixed.

Palates can be used with more than one window.

QuickDraw

An old QuickDraw region bug has been fixed. Performing a region operation (UnionRgn) on two regions that total more than 16K in size used to produce garbage. This is no longer the case.

Painting polygons is now faster and more stable.

Script Manager

The tools and capabilities provided for developers by the Script Manager have been extended in three areas: text, date, and numbers. In addition, some minor bugs were fixed and performance enhancements incorporated.

The new text language routine capabilities include:

- lexically interpreting different scripts (in macro languages, for example)
- allocating justification to different format runs within a line
- ordering format runs properly with bi-directional (Hebrew, Arabic) text
- quickly separating Roman from non-Roman text, and determining word-wrap in text processing.

The international utilities text comparison routines are significantly improved in performance, by 25% to 94%.

The Macintosh date routines are extended to provide a larger range (roughly 35,000 years), and more information. This allows programs that need larger range of dates to use system routines rather than produce their own, which may not be internationally compatible.

The new number routines supplement SANE, allowing applications to display formatted numbers in the manner of Microsoft Excel or 4th Dimension, and to read both formatted and simple numbers. The formatting strings allow natural display and entry of numbers and editing of format strings even though the original numbers and the format strings were entered in a language other than the final user's.

Sound Manager

SndPlay is fixed to work with Format 2 snd resources.

A new resource ID mapping scheme was added for snth resources.

Working MIDI synthesizers are added.

A RAM-based version of Sound Manager to run on the Macintosh Plus and SE is added.

SampledSynth and NoteSynth for the Macintosh Plus and SE are added.

A new version of SystemBeep, for the Macintosh Plus and SE, is added -- with the ability to set a sound to be used with SysBeep.

Sampled Sound Synth can now play at 44.1 kHz sounds without a crash.

The problem of Synth hanging when there is lots of AppleTalk traffic is fixed.

The "Sound" Control Panel device, and its sound list, now appear on the Macintosh Plus and Macintosh SE only if the new sound manager is installed (if the _SndPlay trap exists).

Standard File Package

If CurDirStore or SFSaveDisk is changed when the ReBuildList result is returned from the dialog filter, the current directory is changed to the directory specified by CurDirStore and SFSaveDisk.

System Error Handler

New system errors were assigned for WDEFnFnd (87) and CDEFnFnd (88).

TextEdit

Changes are made to some TextEdit routines, and new routines are added.

The bug in TESTylInsert when inserting 0 length text has been fixed.

ReCalLines has been patched to properly shrink the lineStarts array.

GetStyleScrap was changed to return a proper scrap record, even if there is no selection range (prevents applications from having to special-case insertion points).

References to faces are now byte- instead of word-length.

A bug in TEGetHeight, when there were no characters in the buffer, is fixed. It returned 0 height, but now returns height of the next character to be typed.

Toolbox Event Manager

_WaitNextEvent is now implemented in the System as well as MultiFinder.

Window Manager

A bug was fixed in GrowWindow on the Macintosh II, where it used to return an incorrect result when the window size didn't change.

A bug in WDEF, which caused screen garbage on Macintosh II under rare

circumstances, is fixed.

Macintosh System Software 6.0 Changes (part 3 of 4)

=====

This article last reviewed: 15 June 1988

System File, Continued

New and Changed Resources

ptch	id = 0	TextEdit, no longer in all three PTCH files.
ptch	id = 1	Menu Manager, no longer in Plus & SE PTCH files.
ptch	id = 2	Notification Manager, new (see separate note).
ptch	id = 3	Sound Manager, new and improved.
PTCH	id = -1	Checks for missing patch resources at startup.
MBDF	id = 0	The id has been changed (was MBDF id=8).
vers	id = -2	New 'version' resource for files; see explanation below.
vers	id = -102	New 'version' resource for products; see explanation.

Removed Resources

PACK	id = 4	SANE, floating point package (now in all ROMs).
PACK	id = 5	SANE, elementary math functions (now in all ROMs).
PACK	id = 7	SANE, various conversion routines (now in all ROMs).
WDEF	id = 0	Window definition procedure (now in all ROMs).
DRVr	id = 9	AppleTalk, protocol package handler (now in all ROMs).
DRVr	id = 10	AppleTalk, transaction protocol handler (now in all ROMs).
NBPC	1 & 2	Now obsolete.

Version Resource

To avoid confusion, all system files are now version 6.0, with the exception of the Finder, which is 6.1. With System Software 7.0, ALL files will have the same version number. Other files in the System Software Update now contain "System Software Update 6.0" in the "Get Info" window as well as their logical version number.

The Finder now displays version information according to a file's 'vers' resources.

Fonts

New York 20, 24 and Geneva 20, 24 have been removed from the System on the Utility 1 disk to resolve space problems.

The Chooser

- The bug of not closing device files (except, of course, the current printer) has been fixed.
- Chooser now remembers the window position.
- Chooser now uses the Palette Manager.
- Chooser can now list sounds in the Suitcase files (below the System file).
- The scramble bug, if a cdev (Color) called _DrawDialog, was fixed.

Other Desk Accessories

- The Alarm Clock now remembers the window position. You can now set hours greater than 12 by typing if Alarm Clock was opened in 12-hour mode and then 24-hour mode was set (using the Control panel).
- The Calculator now remembers the window position.
- Find File now remembers the window position.
- Scrapbook now remembers the window position.

Installer Scripts and Resources

PTCH id = -1 is a new patch resource that checks if the machine you are starting up on has the proper PTCH resource(s) in the system file. If the proper patch code is not present, the user can't boot (a message will appear). This was designed specifically for use with MiniScripts (see below), so this patch is installed during MiniScript installation.

The bug of not deleting owned resources unless the owner was in the src file has been fixed.

Empty System files are now created on MFS disks too for installing on blank MFS disks.

The Installer now looks for a AppleShare server before blessed folder.

Font/DA Mover

Support for NFNTs and styled fonts has been added.

A confirmation alert was added for the Remove process.

Finder File

Disk Copy: when copying an entire 800K disk to another, the Finder now uses an "image" copy to create an exact duplicate of the original.

The name of the Print Catalog command has been changed to Print Directory.

The maximum number of windows can be set by changing the last word in the LAYO resource.

MultiFinder File

New Features

MultiFinder now copies the WDs of an application that calls _Launch and includes them in the AppParmHandle.

PrintMonitor is broken down into 5 segments, to allow it to perform in 72K instead of 78K.

Print Monitor now gives visual notification when printing has been stopped via the PrintMonitor window.

MultiFinder Fixes

Double-clicking on a document, when the application is already open, now opens the document. The user no longer sees "The application is already open." Including the resources 'mstr' #102 and 'mstr' #103 in an application allows you to override the default "File" and "Open..." strings respectively when MultiFinder searches for the open menu item. Resources 'mst#' #102 and #103 can be used instead, if necessary (for multiple languages). The Standard File package was patched to implement this.

Background notification support is added. See the section on Notification Manager.

There is a new bit (bit 9) in the SIZE resource, to allow an application to get mouse clicks in its front window during layer switches.

MultiFinder 6.0 does not work with pre System 4.2 files (notified through an alert box). This was done to save 3K on the System Disk.

Developers should be even more careful about fooling around with the enable flag for the Apple menu. In particular, applications are making assumptions that the second item is a dashed line, and then disabling it (often directly and not by calling `_DisableItem`) on the fly. The suggested way to do this is to set the flags correctly in the "Menu" resource for the Apple menu at compile time.

The menu bar Icon no longer inverts during shutdown.

The bug where an application in the foreground should not call `WaitNextEvent` with a sleep value > 50 is fixed.

The bug that would cause an application to crash when selecting a menu key for a pop-up menu has been fixed.

Mouse clicks no longer get lost.

Files opened by an application will be closed, even if the application crashes (MultiFinder monitors the files opened by each application and closes remaining files itself).

MultiFinder no longer crashes with applications that have no Apple menu, but do use hierarchical menus.

String list resources ('mst#',100) and ('mst#', 101) can be used instead of the old 'mstr' strings to override the names used when MultiFinder looks for the "Quit" menu item.

The old `_Launch` call, which applications still use (for example, in `Transfer...` menu items), now just switch to an application that is already running. As a consequence, trying to close the working directory of the launched application's resource file returns an error.

Applications no longer have to pass fake (de)activate events to DAs in their layers when they receive suspend/resume events.

Applications that have the MultiLaunch bit set will no longer lose their SIZE resource attributes if switch-launched from an application other than the Finder.

The "Out of Memory" alert no longer appears if a DA could not be found; a more appropriate message appears.

The clipboard is no longer lost when the user chooses Cut in the Edit menu. It turns out that this never worked!

Before, running two applications with the same name trashed the icon, in the Apple menu, of the launched application when quitting the other. This problem has been fixed.

Resource manager code that was causing crashes because of a bug in the MPW grow zone procedure has been fixed. The problem was that MPW was calling

_CloseResFile inside the grow zone Proc, which was getting called from _GetResource. This caused a reentrancy problem for the MultiFinder resource Manager patches.

Synthesized fonts are no longer being put in the application heap.

MultiFinder's temporary memory requests should be located higher in memory, and are thus less likely to pin down the system heap.

The icon in the menu bar is now exactly the same color as the text in the menu bar.

Background applications that crash before the first call to _GetNextEvent no longer crash the system.

DrawMenuBar will not do anything when called from an application that is in the process of being switched out. This significantly cuts down on menu bar flicker.

Drivers that are part of an application now get SystemTask time if the application gets background time.

MacroMaker no longer crashes with Print Monitor.

Applications that call _Launch on themselves no longer crash.

Mouse-moved events now show up more often. Is is still arguable as to whether they work correctly.

MultiFinder now handles the case where a background application has called _InitWindows, but has not yet called _GetNextEvent. In the past, it would quit or crash. Previously, _ExitToShell would return to the caller.

MultiFinder now calls _Sound Dead when an application quits. This fixes the bug where system beep stopped working.

The bug where despooling would never occur when background printing from a HyperCard script has been fixed.

The bug where booting on a Macintosh II with >1 bit depth and a large number of INITs would crash MultiFinder on startup has been fixed.

Macintosh System Software 6.0 Changes (part 4 of 4)

=====

This article last reviewed: 15 June 1988

PRINTER TOOLS DISK

This disk contains printer drivers for:

- ImageWriter
- AppleTalk ImageWriter
- LaserWriter IISC
- LaserWriter IINT
- LaserWriter IINTX

LaserWriter Driver

Support for 11" x 17" paper is now available via a radio button in the Page Setup dialog box.

The "Page Setup" dialog contains two new check boxes that replace one earlier one:

- The "Text Smoothing" option smooths bitmap fonts that are downloaded.
- The "Graphics Smoothing" option smooths bitmaps other than text.

With the addition of this feature, all previous versions of LaserWriter Prep are incompatible.

LaserWriter 5.2 fixes a problem inherent with printing large bit maps (fonts over 100 points).

Extended rotation picture comments were added, to allow for fractional rotation angles.

A problem with the dashed line comment (the dashed line interval was getting scaled with the pen size) has been fixed.

The srcBic mode (white on black) text problem is fixed (if you drew 2 lines of text in srcBic mode, the second line would not print).

LaserWriter IISC Driver

A problem in the LaserWriter IISC driver that caused icons to disappear when doing the Finder's "Print Catalog" command has been fixed. This problem was introduced in version 1.1B1.

A problem in the LaserWriter IISC driver that caused gaps in straight lines drawn with non-square pen has also been fixed.

A problem in the LaserWriter IISC driver that caused gaps in the outline of a roundRect drawn with a non-square pen has been fixed.

The LaserWriter driver will not print a bitmap if the width or height is zero.

There was a problem in the LaserWriter driver with dashed line intervals. Dashed lines with more than two elements in their patterns did not print correctly. This has been fixed.

A problem with downloading large bitmap fonts (96 points) has been fixed.

MACINTOSH UTILITIES 1

----- HD SC Setup

HD SC Setup was rewritten, for A/UX, to support multiple partitions.

When quitting from HD SC Setup, a call to SCSIDispatch is made with the opcode "QuantumFix".

Mini Installer Scripts

Mini-Scripts creates a system that is appropriate only for the particular Macintosh it was created for. All patches for the other systems are not available when a system is created with mini-scripts. Booting a system configured for one machine on a different flavor Macintosh causes an alert box.

Mini-Scripts are designed to be used on floppy-based systems and to be installed on disks that do NOT currently contain a System. If you install a mini-script over an existing System, you will not get a fully updated System file.

MACINTOSH UTILITIES 2

----- CloseView

The CloseView utility lets users magnify the Macintosh screen, making it easier for visually impaired users to use the computer. It also makes it possible to invert the screen (white on black instead of the usual black on white).

CloseView restores color window manager ports as well as regular window manager ports on screen base address changes.

Map

Map is a Macintosh utility that records and displays the time, longitude, and latitude of locations anywhere in the world.

Problem fixes from older versions: Chicago's time zone has been fixed, and partial names can be used with Find.

MacroMaker

MacroMaker is an Init allowing users to create macros.

Miscellaneous Changes and Problem Fixes

Disk First Aid has been adjusted to support disks larger than 800K.

All Macintosh II patches were changed to support A/UX.

The problem that caused the PRAM on the Macintosh II to sometimes get trashed has been fixed.

If you switch temporarily to one monitor, then back to two, icons on the desktop return to their original positions (unless you move them).

If you try to switch-launch but can't, you are asked to confirm that you want to continue launching the application.

Two problems that caused disk-swapping when switch-launching on a single-drive system have been fixed.

A problem where the 'type' and 'creator' would be written by the application then overwritten by the Finder has been fixed.

The problem that caused a Macintosh to hang if the LAYO spacing was wide and the windows were narrow has been fixed.

A problem with the 'Protect Bit' (AppleShare-related) has been fixed.

LaserWriter IISC: Command-Period Doesn't Cancel Print

=====

This article last reviewed: 3 June 1988

When using the LaserWriter IISC, printing within an application (such as MacPaint) that contains a dialog box requiring the "command-period" to stop printing, you may experience this problem: the "command-period" does NOT stop or interrupt the printing.

However, if you are printing within an application that uses a dialog box with a "cancel" button, the cancel button DOES stop the printing.

This is a problem in the LaserWriter IISC driver, not the PostScript printer drivers. Currently, you CANNOT cancel most print jobs when programs display a printing message stating "To cancel, hold down the command key and type a period (.)"

LaserWriter IINT, IINTX: Icons Disappear from Chooser

=====

Article Created: 2 June 1988

Article Change History

06/09/92 - REVIEWED

- For technical accuracy.

TOPIC -----

When I open the Chooser of my Macintosh, the icon for LaserWriter IINTX is gone. It was there the last time I opened the Chooser, and I have not changed any connections. I am on a network with MS-DOS computers.

DISCUSSION -----

If you have attached your LaserWriter to an MS-DOS computer which has an AppleTalk PC card, and you are running your Macintosh in serial port configuration, and printing to a LaserWriter IINT or LaserWriter IINTX, you may find that the LaserWriter icon appears and disappears at random.

This will probably be true for all other Macintosh computers on the network. As you watch the Choosers, the LaserWriter icons may appear and disappear with no obvious pattern.

This is a normal response to an unworkable configuration. Because of this problem (and possibly others), the "LaserWriter IINT-NTX Owner's Guide" warns that you should disconnect any serial cable attached to the printer before using LocalTalk, and conversely that you disconnect the LocalTalk cable from the printer before connecting a cable to the RS-232 serial port. See the appendix on Connecting to and Printing With an MS-DOS Computer in the "LaserWriter IINT-NTX Owner's Guide" for more information.

LaserWriter and LaserWriter II: Serial Configurations Differ

Revised: 7/27/89
Security: Everyone

LaserWriter and LaserWriter II: Serial Configurations Differ

=====

This article last reviewed: 22 June 1989

The default serial port configuration of the LaserWriter and LaserWriter Plus is: no parity, 8 data bits, 1 stop bit.

The default serial port configuration of the LaserWriter IINT and LaserWriter IINTX is: no parity, 7 data bits, 1 stop bit.

The difference in the default data bits may cause a problem for a PC communicating with

- a LaserWriter IINT in Diablo emulation
- a LaserWriter IINTX in HP LaserJet+ emulation or Diablo emulation (if the PC is configured for communication with a LaserWriter or LaserWriter Plus).

The PC and the LaserWriter must be configured with the same data bit settings. Search on "LaserWriter" and "serial connection" for specific instructions for configuring the LaserWriter and a PC for serial communications.

AppleShare PC and MS-DOS: Memory Problem Workaround

Revised: 5/24/89
Security: Everyone

AppleShare PC and MS-DOS: Memory Problem Workaround

=====

This article last reviewed: 2 June 1988

Some users have experienced a memory problem when trying to load the AppleShare PC software and an MS-DOS application at the same time.

In the MS-DOS world, there are a number of programs that manage DOS TSR (Terminate and Stay Resident) programs. One such program that Apple engineers have used is a public domain package called "TSR 1.7". There are other programs that work in the same manner which may also serve the purpose.

By combining one of these TSR managers and the AppleShare PC software, we were able to load and unload AppleShare PC at will. The basic flow of the MS-DOS .BAT files:

.BAT file to load AppleShare PC

```
ECHO OFF
CD C:\UTILITY
MARK
AppleTalk
CD \ASHAREPC
... rest of AppleShare PC batch file commands
CD \
```

.BAT file to unload AppleShare PC

```
ECHO OFF
CD \ASHAREPC
ANET LOGOFF /ALL          -- Disconnect all connections from
                           AppleShare PC. This is imperative for
                           MS-DOS ReDirector to function properly and
                           AppleShare to know who's logged on at the
                           current time.

CD \UTILITY
RELEASE
CD \
```

```
COMMAND C:\  /P      -- Load a new copy of the DOS Command Processor.  
                        We had some problems with either  
                        AppleShare PC or the TSR Manager and  
                        discovered that reloading COMMAND.COM fixed  
                        the memory problems.  After this command,  
                        DOS is at the root directory.

LaserWriter IINTX LaserJet Emulation: Characters Are Limited

Revised: 9/22/89
Security: Everyone

LaserWriter IINTX LaserJet Emulation: Characters Are Limited

=====

This article last reviewed: 23 August 1989

The LaserWriter IINTX's HP LaserJet+ emulation mode is limited to the Roman-8 symbol set, which prints Courier, Times, and Helvetica typefaces (all the styles of the Roman-8 symbol set).

Math characters are not available in this "standard" character set provided with the HP LaserJet+ printers.

Other characters missing from the LaserJet emulation set:

The gray patch for "rubout" (decimal 127)
Overline (decimal 176)
Degree sign (decimal 179)
Uppercase D with stroke (Eth) (decimal 227)
Lowercase d with stroke (eth) (decimal 228)
Uppercase Thorn (decimal 240)
Lowercase Thorn (decimal 241)
The "one-fourth" symbol (decimal 247)
The "one-half" symbol (decimal 248)
Solid black square (decimal 252)

The one-fourth and one-half symbols are present but appear in a 1/4 and 1/2 configuration instead of the proper:

1	1
-	-
4	and 2

characters.

If these missing characters create a problem, a possible solution is to use a downloadable, bit-mapped font, available from third-party font packages for the HP LaserJet Plus.

AppleTalk: Description of SP_INIT and SP_GET_SESSION

Revised: 11/2/88
Security: Everyone

AppleTalk: Description of SP_INIT and SP_GET_SESSION

=====

This article last reviewed: 3 June 1988

Some users involved in AppleTalk programming have asked for more information about some of the ASP routines described in "Inside AppleTalk" -- especially SP_INIT and SP_GET_SESSION.

The SP_INIT and SP_GET_SESSION routines have been more completely documented in the newest printing of Inside AppleTalk (July 14, 1986).

Here is a reprint of the SP_INIT and SP_GET_SESSION documentation from section XI, pages 6 and 7:

Before any workstation can open a session with a server, the server's SLS must be established. This must be done by the ASP client at the server end. This client must issue an OPEN-ATP-Responding-socket call to create the SLS. Then it must call NBP to register the appropriate server entity name on this socket. At this point, the SLS is set up so that a workstation can discover its own network address through an NBP lookup.

However, a workstation still cannot open sessions with this client entity. For this purpose, the ASP client in the server must now issue an SPInit call to ASP (passing to ASP the network address, known as the SLSEntityIdentifier), followed by one or more SPGetSession calls.

SP_Init

Inputs:

SLSEntityIdentifier -- SLS network identifier
ServiceStatusBlock -- block with status information
ServiceStatusBlockSize -- size of status information block

Outputs:

SPError -- error code returned by ASP
SLSRefNum -- reference number for SLS

Errors:

TooManyClients -- ASP implementation cannot support another client
SizeErr -- ServiceStatusBlockSize is greater than QuantumSize

This call is issued by the ASP client after having opened and named the SLS. The call passes the (network-dependent) SLSEntityIdentifier to ASP as well as a ServiceStatusBlock. This block is used to hold the service status information to be returned in reply to GetStatus request received at the SLS. The SLSEntityIdentifier is the complete internet address of the SLS.

SPInit returns the SLSRefNum (this is unique among all SLSs on the same server node) that is used in the SPGetSession call to make reference to the SLS passed in the SPInit call.

SP_Get_Session

Inputs:

SLSRefNum -- reference number for the SLS

Outputs:

SPError -- error code returned by ASP
SessRefNum -- session reference number

Errors:

ParamErr -- unknown SLSRefNum
NoMoreSessions -- implementation cannot support another session

This call is issued by the ASP client to allow it to accept an OpenSession command received on the SLS identified by the SLSRefNum. Each SPGetSession request authorizes ASP to accept one more OpenSession request.

The call completes when such a request is received on the SLS and a corresponding session has been opened. The SessRefNum is returned to the server ASP client and must be used in all further calls to ASP that refer to this session.

Clearly, the SessRefNum must be unique among all sessions open to the server.

Apple/DEC Alliance and AppleTalk for VMS

Revised: 11/2/88
Security: Everyone

Apple/DEC Alliance and "AppleTalk for VMS"

=====

This article last reviewed: 3 June 1988

In January 1988, Apple Computer and Digital Equipment announced a joint development agreement under which the two companies would work together to integrate Macintosh and the AppleTalk network system with the VAX and DECnet.

Apple and DEC are focusing on nine areas of development. Some of these areas (such as mail, distributed applications, and terminal emulation) will result in specifications and tools that allow third parties to build even greater functionality into their future products. In other areas, the two companies will work together at the fundamental architectural level to create new products (for example, tools that allow network managers, using DECnet network management, to view and manage a combined AppleTalk/DECnet network as a single entity).

The good news for customers is that many of the capabilities discussed by Apple and DEC are available today from third parties, and these products have been built on the architecture that Apple and DEC have endorsed. Since Apple and DEC will be making development specifications available to these third parties, they will be able to engineer their products to take full advantage of the Apple/DEC development efforts.

In summary, Apple and DEC have agreed to lay the foundation for compatibility and cooperation between Macintosh/AppleTalk and VAX/DECnet. This foundation includes specifications and tools that allow developers to build products with greater functionality.

However, it is not necessary to wait for the Apple/Digital agreement. Alisa Systems, Odesta, Pacer Software, and Telos have products based on "AppleTalk for VMS", which is one of the first tools available.

- Thursby Software's NSSnet, distributed by Alisa, fully supports DECnet protocols.

..TIL03046-Apple-DEC_Alliance_and_AppleTalk_for_VMS_(TA38504).pdf

- All-in-1 support is available from Telos Software with their MacNOW product.
- Color terminal emulation is available using VersaTerm or VersaTerm-PRO.

For more information, search under: Alisa Systems, Odesta Corporation, Pacer Software, Telos Software, VersaTerm.

AppleShare PC: Mapping Lotus Files for Excel

Revised: 10/18/88
Security: Everyone

AppleShare PC: Mapping Lotus Files for Excel

=====

This article last reviewed: 3 June 1988

If you are using AppleShare to store Lotus files for access from Excel, you may have had a problem like this:

When a Lotus worksheet is copied to AppleShare, it gets TYPE-set to "J123" and CREATOR-set to "MJAZ" (Modern Jazz settings). This file, however, is not recognized by Excel. If you use Apple File Exchange to copy the SAME file from a 5.25" drive, it gets TYPE-set to "BINA" and CREATOR-set to "mdos", which Excel accepts, and the file opens.

You have encountered the default Extension Mapping of AppleShare PC. Control of Extension Mapping is under the "Special" menu of DA (our AppleShare PC program) using the "Change Extension Mappings" item.

AppleShare PC automatically sets a Macintosh file icon-type for files created on file server volumes. These type assignments are based on the three-character DOS filename extension.

"Change Extension Mapping" lets you select an icon-type for a file extension. This icon-type is assigned to all appropriate new files created on server volumes; existing files are not affected.

In the example problem given above, the WKS and WK1 extensions from Lotus 1,2,3 default to an extension map called "JAZZ-Lotus" instead of mapping to "Excel".

To change this mapping for all new files created, select the "Change Extension Mapping" item from the DA "Special" menu. A dialog (or pane) displays something similar to "Extension: XXX = Binary", followed by a scroll box "Select Type:". Use the cursor keys to scroll to and highlight item number 4, which is the map called "Excel". Press F2 to reset the map from "JAZZ-Lotus" to "Excel".

Until this process is reversed, all new files are saved with the Excel map.

All existing files need to be reopened and saved under a new name for this mapping to affect them. Once saved with the Excel mapping, double clicking the documents launches Excel. The documents have a "plain" document icon.

Any DOS document can be forced to have the

TYPE-set = BINA and CREATOR-set = mdos

by adding an unmapped extension to the end of the of the document name. For example, when saving the document "Anything.ABC", AppleShare PC provides the BINA/mdos labels. To view the mapping of any given PC, type:

anet map

This lists currently assigned extensions and their mapping.

European Apple II: No Color With U.S. Monitor (2/97)

Article Created: 01 July 1988
Article Reviewed/Updated: 17 February 1997

TOPIC -----

This article discusses the problem of the European Apple II not producing color when used with a U.S. Apple Color Monitor.

DISCUSSION -----

A European Apple II produces either PAL or SECAM video output, both of which are compatible with European television standards. However, these signals are incompatible with the NTSC signal required for U.S. monitors. The signal is close enough in video content to be resolved in black and white, but the frequency of the color burst is incorrect for an NTSC monitor.

Using a European Apple II system in North America, you can get an acceptable color display from your European monitor, although there may be some problems due to the different line frequency in North America.

Security: Everyone

LaserWriter and System Software for Mixed Installations

=====

This article last reviewed: 16 June 1988

Anyone dealing with a variety of Macintosh models (including Macintosh 512Ke systems) in work group networks with a recent LaserWriter model (such as the LaserWriter IINT) needs to be aware of the different combinations of System/Finder versions and LaserWriter software. The Tech Info Library article "Macintosh: Recommended System Software Configurations" contains most of the information needed to determine which System/Finder versions to use on each system.

LaserWriter versions later than 4.0 offer the advantages of faster and larger bitmap printing and overall faster operation. However, Apple does not recommend the use of LaserWriter drivers later than 4.0 when using Macintosh 512K or 512Ke systems.

Macintosh II: NuBus Problems and ROM Upgrade (9/95)

Revised: 9/1/95
Security: Everyone

Macintosh II: NuBus Problems and ROM Upgrade (9/95)

Article Created: 16 June 1988
Article Reviewed/Updated: 1 September 1995

TOPIC -----

The original release of the Macintosh II ROM had a problem in the Slot Manager. Units shipped after February 1, 1988, contain an upgraded ROM. If your Macintosh was built after that date, or if you do not use a NuBus card that addresses over 1MB, the Slot Manager problem does not affect you.

DISCUSSION -----

The Slot Manager is a section of the Macintosh II ROM that contains a set of routines that makes it possible to identify and communicate with cards plugged into NuBus slots in the Macintosh II.

The problem is that the Slot Manager does not recognize cards that need more than 1MB of address space to function. This is because the Slot Manager runs in the 24-bit addressing mode and should be running in the 32-bit addressing mode.

The 68020 uses these two modes for interpreting memory addresses. In the 24-bit mode, the Macintosh can access only 1MB of memory for each card. If the card exceeds this limit, the Macintosh won't recognize that the card is in the slot. This is because of the way Apple recommends that developers format their cards. If the card can fit all of its code into 1MB, there is no problem.

For details on Macintosh operation in either 32-bit or 24-bit mode, see the Operating System Utilities chapter of "Inside Macintosh, Volume V" (ISBN 0-201-17719-6). For details on the use of address space by NuBus cards, see Chapter 4 of "Designing Cards and Drivers for Macintosh II and Macintosh SE" (ISBN 0-201-19256-X).

Identifying Your ROM Version

The problem was fixed via a patch to the Macintosh II ROMs and was rolled into production around February, 1988. All Macintosh IIs manufactured since then

have the fix installed.

You can identify the upgraded ROM by "Revision B" on the chip. In addition, manufacturers of NuBus cards requiring the fix usually included a small software application that can be run to determine if you have the new ROM. Apple-authorized service providers may also have this application.

Please note that the change to the Macintosh ROM was done as an object overlay only. This means that the object code was patched, and the ROM was not rebuilt.

Only minor changes were made to allow the Slot Manager to work in 32-bit mode instead of 24-bit mode, thus ensuring that it recognizes cards requiring more than 1MB of address space.

The Upgrade Program

Because of the Slot Manager problem, Apple patched the ROM and offered a free upgrade program to customers who bought NuBus cards requiring this fix.

The service program to replace the logic board has expired. Logic boards experiencing this issue can be replaced, but it will not be a free replacement.

Article Change History:

01 Sep 1995 - Combined information from several articles for consistency.
23 Dec 1994 - Noted that SuperDrive upgrade requires Rev. B logic board.

Macintosh System 6.0 Installation Recommendations

Revised: 8/1/88
Security: Everyone

Macintosh System 6.0 Installation Recommendations

=====

This article last reviewed: 16 June 1988

When updating Macintosh system software to version 6.0, be sure to start up from the System Tools disk. Do not just switch-launch to it. Without a clean restart, programs and INITs can interfere with proper installation.

After performing what seemed to be proper installations on a variety of Macintoshes, engineers were getting consistent (though sometimes intermittent) error messages when restarting the systems. The errors included:

- "Unable to load needed resources" on startup.
- ID errors 02, 07, 10, 11, etc. when running applications or performing simple events.
- RAM Cache could be changed only to 1596.

These errors varied, depending on the type of Macintosh on which the installation was performed and the types of CDevs and INITs contained in the System files when upgraded. For example, it mattered if either Menu Clock or Vaccine (even though turned off) were present.

The above errors disappeared after deleting the recently updated System Folder, restarting the Macintosh with the System Tools disk, and reinstalling the software. Therefore, always start up from the Installer disk when installing or upgrading software to ensure a complete installation takes place.

This article last reviewed: 16 June 1988

MacTerminal 2.3 does not use the function keys on the extended keyboard. However, it still contains the PF key menu for VT100 and IBM 3278 as in previous versions. You can use MacroMaker to select the keys, and then assign a recording of the PF key menu selection to each function key. You can also type and record keyboard sequence with MacroMaker.

The key sequences for the VT100 PF keys are: (ESC OP)=PF1, (ESC OQ)=PF2, (ESC OR)=PF3, (ESC OS)=PF4.

The IBM 3278 PF keys are:

Key Sequence	Menu option
[ESC 1, ESC 2,... ESC 9, ESC 0, ESC -, ESC =]	= PF1, PF2, ... PF12
[ESC !, ESC @,... ESC (, ESC), ESC _, ESC +]	= PF13, PF14, ... PF 24
[ESC [, ESC],	= PA 1 and PA 2

ASCII	Key Sequence	Menu option
<SOH>	= CONTROL A	= Attn
<DLE>	= CONTROL P	= Home
<FS>	= CONTROL \	= Print
<ACK>	= CONTROL F	= Erase EOF
	= CONTROL (Backspace or Delete)	= Delete
<FF>	= CONTROL L	= Erase Input
<GS>	= CONTROL]	= Insert
<DC2>	= CONTROL R	= Reset
<STX>	= CONTROL B	= Sys Req
<ENQ>	= CONTROL E	= Clear

PICT 2 Files Supported by Third-Party Applications

=====

Article Created: 16 June 1988
Article Last Reviewed: 20 May 1992
Article Last Updated: 4 August 1989

Some applications require PICT 2 files. This has created interest in how a user can "create" or convert PICT 2 files.

"PICT 2" refers to the PICT version 2 format documented in "Inside Macintosh Volume V" under Color QuickDraw. The file format defines color PICT support - something previously not implemented.

A number of third-party applications support the color PICT format. Most scanners and digitizers support the color PICT format, as do many color or grayscale paint applications. Pixel Paint, for example, reads and writes a number of different formats, including color PICT and MacPaint. Also, the shareware application Giffer reads PICT 1 files (MacDraw PICT) and saves them as PICT 2. It opens both PICT formats but writes only the PICT 2 format. Giffer also converts other file types commonly found on bulletin board systems.

PostScript: Displaying It on the Macintosh Screen

=====

This article last reviewed: 16 June 1988

Macintosh print drivers let you view PostScript commands for editing purposes. Before printing, press and hold the Command and "F" keys after selecting OK from the print dialog box. You'll see the message "Creating PostScript File." The file is named PostScript0, PostScript1, etc. -- a standard text file that can be opened by most word processing and text editing programs.

Apple has no plans to display graphics based on PostScript language routines. Nor are any third-party companies working on such a large project. This capability would require a rewrite of the Macintosh operating system so that it displayed graphics via PostScript instead of QuickDraw.

AppleLine and IBM 3174 Controller Upgrade

=====

This article last reviewed: 16 June 1988

IBM has recently upgraded the microcode for IBM 3174 controllers. Versions 3.0 and 3.1 allow command chaining, an enhancement for the 3174's that increases throughput.

The increase in speed has caused a problem with the timing within AppleLine. This problem appears as half displayed screens. The effect is not dramatic, but it is a nuisance. To refresh the screen, type Control-C.

Apple is studying compatibility between AppleLine and the new 3174 controller code.

Macintosh II Screen And NTSC Video Camera Synchronization

Revised: 7/2/92
Security: Everyone

Macintosh II Screen And NTSC Video Camera Synchronization

=====

Article Created: 21 June 1988
Article Last Reviewed: 30 June 1992
Article Last Updated:

TOPIC -----

This article discusses methods of synchronizing video camera output with the Macintosh II screen. Read the entire article, including warnings, before attempting any of the procedures described.

There is another article that describes VideoSync, a software product from Apple which may be a solution as well. Search under "VideoSync" for more info.

DISCUSSION -----

Some video boards currently provide NTSC output. However, these conversions do not solve the problem of screen flicker that a camera records. The problem is inherent in NTSC and PAL standards, because they impose limitations based on screen resolutions and display rates.

Screen flicker, as recorded by video cameras, occurs because the scan rates of NTSC and PAL video cameras are slower than the scan rates of high resolution RGB monitors like the Macintosh II monitor. PAL rates of 50 Hz make the flickering image worse.

RESETTING TO RS-170 MODE

Parameters on the Macintosh II video card can be set for an RS-170 mode. RS-170 is an interlaced 59.97 Hz signal. While the board is capable of a 60 Hz RS-170 Mode (nearer to the NTSC rate), the problem of screen refresh remains. At the 60 Hz setting, the card operates an interlace scan that causes fields to be updated at 30 Hz (because of the odd and even retrace of lines that occurs in 60 Hz interlace mode). This produces an NTSC signal on the green pin without the color burst (black and white video).

This signal is not compatible with Apple High Resolution Monitors, but can be viewed in color from a MultiSync monitor or an Apple Color RGB monitor when the red, green, and blue video lines are connected.

ANOTHER SOLUTION

Because of the extended retrace time of 60Hz interlace, the phosphor decay rate of most monitors causes the phosphors to "turn off" long before the phosphor is rescanned. This causes flickering. To correct this, do either of two things:

- Use high persistence phosphors (Princeton Graphics and Commodore carry long persistence phosphor displays).
- Set the video card to display 60 Hz non-interlace (progressive scan). This cannot be done through software. It is possible only by a hardware modification to the card.

THE MODIFICATION

NOTE: For those lacking the technical resources for this modification, TVA Production Services provides a computer synchronization service. TVA has been synching computers since 1983 and has the experience necessary to successfully synchronize your computer.

You will need a new pixel clock (to replace the 30.24 Mhz clock on the video card) or an external pixel clock generator. If you have a variable clock generator, you can probably do the necessary slowing of the video signal. Simply remove the oscillator from the card and substitute your pixel clock signal.

However, this will not synchronize the camera to the screen. As a result, a visible horizontal retrace line might appear from the offset of the two timings. The best method is to use an external adjustable clock and "tune" it to move the retrace line off the screen. Finally, reset to the proper clock timing.

You may have noticed that a clock is not the same as the sync. The clock is the master timing device that controls each pixel period and all timing parameters--including vertical and horizontal scans. The vertical sync is normally 66.67 Hz and the horizontal sync is 35Khz on a Macintosh II video card. A 59.94 Hz non-interlaced screen for the Macintosh II video needs an oscillator (pixel clock) of 27.188807 Mhz.

If you do not want to remove the clock, do two things. First, ground pin 14 of the J3 connector on the card (pins 1,2,3,5,7,9, and 11 of J3 are grounds). Second, connect the external clock to pin 4 of the J3 connector. This will cause the external clock to be selected over the Macintosh II video card's 30.24 Mhz oscillator. Most signal synthesizers provide a BNC signal function-out connector.

Note: The J3 connector is not the external port but a connector on the video card. Usually, it is located under the serial number sticker.

The generator must be on for the video card to function. Set the waveform for a 5-volt square wave at 27.188807 MHz. This method also voids your warranty. The pinouts and signal descriptions of the Macintosh II Video Card are in the article, "Macintosh II Video Signals."

On an Apple High Resolution RGB Monitor, using a 27.188807 MHz clock, the video locks at 59.94 Hz, but still needs to be adjusted for horizontal sync.

WARNING: This technique voids any warranty on the monitor and may result in damage to the monitor and even physical injury to an untrained technician.

To make this adjustment, tune the H-Hold pot on the main logic board of the monitor. If the display fails to black, it is probably because the H-Hold pot is out of adjustment.

Note: RasterOps makes a video board which can accomplish this as well.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

LocalTalk PC Card: IRQ Issues

Revised: 12/19/91
Security: Everyone

LocalTalk PC Card: IRQ Issues

=====

Article Created: 23 June 1988
Article Last Reviewed: 30 July 1992
Article Last Updated: 30 July 1992

TOPIC -----

The LocalTalk (formerly known as "AppleTalk") PC Card can function only with IRQ (interrupt request priorities) 2, IRQ 3, or IRQ 4.

DISCUSSION -----

Many users of the LocalTalk PC Card have found that if the IBM PC has two serial ports, each serial port uses an IRQ, and that the PC itself uses the third one - leaving none available for the LocalTalk PC Card.

The best solution is to move one of the IRQ lines coming from one of the serial ports (examine the manufacturer's instructions before doing this) to an IRQ number that can't be used by the LocalTalk PC Card - like IRQ 5. Then, the LocalTalk PC Card can use the newly-available IRQ line 2, 3, or 4.

Users who have installed LocalTalk PC cards in IBM PC-ATs find that nearly all of the IBM PC-ATs use both COM1 and COM2. So, using IRQ priority level 4 or 3 is not possible, and they are forced to consider using IRQ2 -- but the LocalTalk PC card manual states: "Do NOT use switch 3 (IRQ2) if you have an IBM PC-AT computer."

Fortunately, if you have AppleShare PC 2.0, this configuration (using IRQ priority level 2) should work fine.

Quoting the README.DOC file on the AppleShare PC disk:

"The 2.0 version of the LocalTalk PC Card driver (AppleTalk.EXE, included on this disk) does not use the card's hardware interrupt feature. This means that the default card settings will not conflict with a COM2 serial port,

as your card manual indicates. The 2.0 driver ignores the /cardint command line parameter."

Some users of the LocalTalk PC card have reported problems after installing the card and changing the IRQ (Interrupt Request line). Symptoms have included:

- When printing to "*", the LaserWriter just hangs.
- Selecting a printer causes the "Looking for AppleTalk Zones" to blink forever.
- AppleShare hangs also.
- Inter-Poll can't see anything from the outside.
- Reloading software doesn't help.
- Reducing the number of machines on the network doesn't help.
- Changing LocalTalk PC cards doesn't help.

The key is that you must tell DOS when you change IRQs. To do this, put the command "/cardint=x" in the AUTOEXEC.BAT file of your boot disk, where x is the new IRQ level (either 2 or 4). Check the LocalTalk PC card manual under the subtitle "Driver configuration options" for more information.

Note: The LocalTalk PC Card is now owned, sold, distributed and supported by Farallon Computing. Search under "Farallon" for contact information.

ProDOS 1.4 And Backup II 1.1 Incompatibility: Use ProDOS 1.1.1

=====

This article last reviewed: 23 June 1988

ProDOS version 1.4 does not work properly with Backup II version 1.1 -- using them together results in "random errors". If you already have Backup II v1.1, you can work around the problem by launching with a disk configured for ProDOS 1.1.1.

This incompatibility has been solved in the current version of Backup II (v1.1.1), which will function perfectly well with ProDOS 1.4, and which also solves some other problems found in Backup II v1.1, such as failures of the "restore" function.

TOPS Installer: Problem With System Incompatibility

=====

This article last reviewed: 23 June 1988

Some users who have multi-Macintosh networks (all running the most current System) using TOPS as a file server have experienced system bombs and problems initializing new disks.

TOPS comes on a single-sided disk that also contains System 3.2. When TOPS is installed from this original disk, it copies resources from System 3.2 and places them in the System file of the destination volume -- usually a more current system, incompatible with System 3.2.

The solution is to copy TOPS from its original disk onto a double-sided disk (current systems will not fit on a single-sided disk), then use the System Installer to update this new disk with the version of System and Finder your destination volume is using. Now TOPS can be installed without causing problems.

Apple FAX Modem Work With Any Standard FAX

=====

This article last reviewed: 13 July 1988

Apple's FAX modem, operating over normal telephone lines, will transmit or receive documents with any FAX device that supports the CCITT Group 3 FAX standard.

All modems take digital information and modulate it into analog form when sending a file. The information is then demodulated into digital form when the file is received.

The CCITT Group 3 standard is in use by the majority of installed FAX devices.

EtherTalk and AppleTalk bridges: An Installation Example

Revised: 11/2/88
Security: Everyone

EtherTalk and AppleTalk bridges: An Installation Example

=====

This article last reviewed: 27 June 1988

Here is a brief description of a corporation's Ethernet installation. They have used Ethernet as the primary communications medium for achieving transparent connectivity throughout the system.

Number of segments	> 50
Number of nodes	>500
Span of network	> 20 KM (using Ethernet bridges)
Number of campuses	4
Number of Kinetics FastPath Gateways	= 9

When a Macintosh communicates with a device on another network, it routes packets over AppleTalk bridges. The Macintosh's RTMP stub algorithm does not keep track of which bridge supports which Network ID. Rather, it listens to RTMP routing packets and keeps track of which one it heard from last.

When the Macintosh is ready to transmit a packet to another network, it sends the packet to the bridge it heard from last. This bridge then forwards the packet to the correct bridge, which then completes the request. The Macintosh uses this two-bridge routing throughout the transfer.

If the intermediate bridge is on another campus or in another state, this algorithm can seriously affect throughput and Ethernet loading. For example, printing to an Apple LaserWriter is approximately 25% slower on Ethernet than on LocalTalk.

Is there a suggested solution for this problem?

The speed decrease is accurate. When printing, the packets must cross LocalTalk to get to the printer. For example, assign a time unit of 4 to identify the time a packet takes to travel across a LocalTalk network and a time unit of 1 to a large EtherTalk network. Thus, a packet crossing EtherTalk and LocalTalk to a LocalTalk device takes a total of 5 time units, whereas a packet on the LocalTalk network takes only 4 time units.

The EtherTalk-originated packets cannot move "faster" than those from a LocalTalk system on a LocalTalk network. The EtherTalk packets additionally must travel across the EtherTalk network to get to the LocalTalk network. To decrease the time it takes to get control back when printing, use LaserShare servers connected directly to Ethernet with EtherTalk boards. This eliminates the LocalTalk slowdown.

The routing of the RTMP packets is a problem, which Apple is looking into. Part of the reason is because AppleTalk was created on the 128K and 512K Macintoshes, and memory was not available for large routing tables capable of mapping a large network. The time difference while taking trips to the source of the last RTMP packet is generally not significant.

The Apple specifications for the RTMP suggest 10-second update periods. This time has been found to work correctly at sites with 60 or more FastPaths. If you have trouble with extreme slowdowns, troubleshoot the network. That is, reinstall software and check all Net and Zone ID's. One site (containing a large, varied network) was able to remove a network zone-delay problem by updating all FastPaths and InterBridges to current ROM and Software levels.

EtherTalk: The Number of Possible Nodes in a System

Revised: 7/13/88
Security: Everyone

EtherTalk: The Number of Possible Nodes in a System

=====

This article last reviewed: 27 June 1988

Here is a brief description of a corporation's EtherNet installation. They have used Ethernet as the primary communications medium for achieving transparent connectivity throughout the system.

Number of segments	> 50
Number of nodes	>500
Span of network	> 20 KM (using Ethernet bridges)
Number of campuses	4
Number of Kinetics FastPath Gateways	= 9

The current Node ID field allows only 127 individual stations. Does that mean only 128 Macintosh computers can be connected directly to the Ethernet? What about software bridges like Liaison? What about GatorBox, which promises to become the InterBridge of EtherTalk?

EtherTalk makes no distinction (through node IDs) between users and servers. Rather, it reserves two nodes for "send to self" and "send to all" addresses. This leaves 254 of 256 possible nodes available for users and servers.

Customers use Zone and Net IDs to divide users into zones. Gatorbox's Ethernet-to-Ethernet bridging capabilities allow EtherTalk networks to extend well beyond the 254 nodes available. Under Gatorbox, you can directly connect Ethernet Macintoshes by routing Zone and Net IDs similar to the zoning done with InterBridges.

A/UX: Setting "sash" Variable From the Menu

Article Created: 29 June 1988

Article Change History

08/31/92 - REVIEWED
• For technical accuracy.

TOPIC -----

Setting "sash" Variable From the Menu

DISCUSSION -----

If the root directory controller number is changed in the Preferences menu, the "sash" variable is not adjusted to the new value. To pick up the change, you have quit from the "sash" and rerun it.

Normally, when "sash" is first invoked, it performs a "chroot" command to whatever "sash" variable "ROOT" was set to in a previous session. If the root directory controller number in the menu is changed, the "sash" variable "ROOT" changes to that number -- but it is not "export"ed.

To launch A/UX from a different drive, choose either of the following methods:

- Issue the "launch (x, y, z)/unix" command.
- or -
- 1) Issue the "chroot (x, y, z)" command (where x is the SCSI ID, y is SCSI subdrive ID, and z is the slice number in the drive).
- 2) Then issue the "launch" command. (Selecting a different controller number from the menu or setting the variable "ROOT" immediately does not affect the change on the root directory.)

Inter•Poll: Why It Doesn't Detect Bridges or Gateways

Revised: 3/1/93
Security: Everyone

Inter•Poll: Why It Doesn't Detect Bridges or Gateways

=====

This article last reviewed: 29 June 1988

Some users have noticed that Inter•Poll only displays local bridges when encountering bridges or gateways, like a FastPath. For example, in an office with an Ethernet backbone and three Kinetics FastPaths, Inter•Poll finds all devices on AppleTalk and Ethernet. However, it ignores two FastPaths that reside outside the Inter•Poll workstation zone.

The reason for this is that unnamed network devices, like bridges or gateways, do not respond to echo packets outside their assigned networks. Therefore, Inter•Poll fails to detect bridges and gateways located beyond the local network.

NuBus Card: Parts for Custom-Building

=====
Article Created: 29 June 1988
Article Last Reviewed: 16 June 1992
Article Last Updated:

TOPIC -----

This article contains questions and answers about sources and specifications, for anyone interested in building a NuBus video card to drive multiple displays from one board.

DISCUSSION -----

- Where do you purchase male DIN 8 connectors?

Male DIN 8 connectors are available from Advanced Electronic Support Products, Inc. (AESP).

- What is the Belden part number for the video cable used by Apple? If this is not available, what is the cable configuration, and can it be expanded to 50 feet?

The Macintosh II video cable is custom built for Apple. However, companies (like Advanced Electronic Support Products) manufacture cables to client specifications.

Here is the cable configuration. There are four video signals and four ground pins on the Macintosh II video card DB-15 female connector:

- 1 RED VIDEO GROUND
- 2 RED (analog)
- 3 CSYNC* (TTL) used by Apple Displays
- 4 CSYNC GROUND
- 5 GREEN + CSYNC (analog) used for monochrome; CSYNC not used by Apple displays
- 6 GREEN CSYNC GROUND

9	BLUE	(analog)
12	GREEN + CSYNC	(analog) not used
13	BLUE VIDEO GROUND	

*Composite sync (vertical and horizontal).

A custom video extension cable for a Macintosh II requires a cable with a 75-ohm impedance value (usually RG59U standard coaxial video cable). Each line ties to the appropriate pin at the connector, and the shield is connected to the signal ground pin.

Impedance: 75 ohm
Signal Strength: 13.33 amps, 1 volt

The video signal can be extended 1,000 feet (although there is some color loss at this distance). The signal should be reliable up to 50 feet. The distance is limited by the loss of signal strength through cable resistance.

For more information on pin-outs, cable wiring, and technical specifications, search on "Macintosh II Video Signals".

- Who manufactures the edge connectors--the connector that goes out the back of the Macintosh II, not the motherboard connector--for the NuBus cards?

A source for the video connectors (Part Number:745782-6) is AMP, Inc., of Southeastern, PA.

SCSI Cable Connection and Termination

Revised: 7/8/92
Security: Everyone

SCSI Cable Connection and Termination

=====

Article Created: 29 June 1988
Article Last Reviewed: 9 July 1992
Article Last Updated: 9 July 1992

TOPIC -----

This article answers three questions about SCSI cable connection and termination. The answers are most significant where users share SCSI devices.

DISCUSSION -----

1. Can a SCSI system cable with terminator be left connected to a Macintosh without the other cable end being attached to a SCSI device?

Yes, the SCSI can be terminated and connected. There shouldn't be any difficulties with this setup.

2. If a SCSI peripheral is attached (for example, system cable to HD 80SC), can the SCSI extender or SCSI peripheral cable be attached to the last "real" SCSI device with the other end of the cable left unattached?

SCSI cables can be connected to the last SCSI device in the chain, provided they are terminated.

3. Does a terminator go on the last device, or at the end of the last piece of cable?

As long as these cables are connected, they are considered part of the SCSI bus -- whether connected to a device or not. As part of the bus, you need to terminate the cables.

MacTerminal: MacroMaker for Sending Escape Sequences

Revised: 6/24/90
Security: Everyone

MacTerminal: MacroMaker for Sending Escape Sequences

=====

This article last reviewed: 29 June 1988

Some users want to send application commands with the keypad in VT100 mode. However, when using MTMOD, the keypad sends only the character code for the number, while showing the correct setting on the screen. For example, when you press the "9" on the keypad, MacTerminal sends "9" instead of Esc,"O","Y".

To send an escape sequence instead of a number use MacroMaker, part of the recently released System Software 6.0. MacroMaker can send the escape sequence correctly. You can redefine the "9" on the keypad, because MacroMaker understands the keypad as a separate set of keys.

Note: MTMOD does not work with later versions of MacTerminal.

Macintosh Boot Block: General Information

Revised: 7/13/88
Security: Everyone

Macintosh Boot Block: General Information

=====

This article last reviewed: 29 June 1988

Here are three questions about boot blocks and how they are copied to System disks. The appropriate answer follows each question.

1. When are the boot blocks copied to a new hard disk or floppy?

The boot blocks are copied to a new hard disk or floppy disk when you copy a System file to the disk.

2. Are the boot blocks taken from the "boot" resource in the System file being copied or from the boot blocks on the source disk?

The boot blocks are taken from the source disk unless that disk does not have a valid copy of the boot blocks or the disk is a file server. In these cases, the boot blocks are taken from the "boot" resource in the System file being copied.

3. Are the boot blocks rewritten when copying a new System and Finder to a System disk?

Yes, the boot blocks are rewritten when copying a new System file to a disk.

HyperCard and Excessive Disk Access

Revised: 6/24/90
Security: Everyone

HyperCard and Excessive Disk Access

=====

This article last reviewed: 29 June 1988

Some users have reported seemingly continuous disk activity when running large HyperCard stacks (in one case, 13000 cards amounting to 3.8M of disk space). Disconnecting from a network made no difference.

The probable reason for continuous access is a HyperTalk statement that adds or changes information in a field on a card. Any of three commands (particularly when paired with a large number of cards) can contribute to excessive disk access:

- the time
- the long time
- on idle

Putting "the time" into a field changes the field and thereby initiates drive access -- once every minute.

Putting "the long time" into a field causes access once every second! HyperCard performance may suffer from such continual disk I/O process.

Also, an "on idle" routine in a stack script or a card script of the current card initiates disk I/O, because it adds or updates information within the stack.

Slow down with large stacks also occurs when HyperCard preloads card index pages during idle time. With many cards, there are many card index pages. The first pages are unloaded when the latter ones are loaded. Therefore, HyperCard keeps loading them, which results in the disk activity. HyperCard 1.2 seems to correct the problem.

To summarize: where appropriate, change from "the long time" to "the time" and review the use of "on idle" routines. Also check for any XCMDs and XFCNs that may be initiating disk activity.

Macintosh System Software 6.0 Compatibility Report (Part 1 of 3)

Revised: 5/31/89
Security: Everyone

Macintosh System Software 6.0 Compatibility Report (Part 1 of 3)

=====

This article last reviewed: 29 June 1988

This is the first part of a three part article:

System Software 6.0 Compatibility Report

This is a list of third-party software applications that have been tested by Apple with System Software 6.0.

(NOTE: This report does not cover all Macintosh application software, only those applications that have been reviewed by Apple. For more detailed information on the compatibility of any application with System Software 6.0, please contact the developer or publisher of the software in question.)

This examination did not test every feature of the application. Instead, each application was run through a series of "quick looks" -- launch, open a simple document, open DAs, Cut/Paste, and print.

This report reflects compatibility information on the version number of the application listed, and does not necessarily reflect the most current version of a particular application.

Testing was done on Macintosh(R) Plus, Macintosh SE and Macintosh II personal computers using System Software 6.0. Single Finder was not used unless a memory constraint existed. Ratings for all applications indicate performance of the application running on release CPUs and released System Software.

Where possible, Apple will update this list with new information. Please check HotLinks on AppleLink for updated versions of this report.

The following applications have been rated with an 'A' status.
A = The application runs under System Software 6.0.

Product	CPU	Company
Intermail 1.42	ALL	Interactive
LightSpeed C 2.15	ALL	Think Technologies
Mac3D 2.0	Mac +, SE	Challenger SW
SmartCom II 2.0	ALL	Hayes
ComServe 1.0	ALL	Info Sphere Inc.
DeskTop Express 1.0	ALL	Dow Jones
Dow Jones MMGR+ 1.01	ALL	Dow Jones

LaserWriter IINTX: PostScript Batch Mode For Serial PCs (8/95)

Revised: 8/23/95
Security: Everyone

LaserWriter IINTX: PostScript Batch Mode For Serial PCs (8/95)

=====

Article Created: 13 July 1988
Article Reviewed/Updated: 22 August 1995

TOPIC -----

This article describes printing from a PC using a serial connection.

DISCUSSION -----

If you need to print with LaserWriter IINTX in PostScript batch mode, here is the method for serial connection from a PC:

Step 1: Connection

Connect a serial cable from the PC serial port to the printer serial port.

Step 2: Switch Settings

While the LaserWriter IINTX is off, set the printers DIP switch settings to:

- 1 UP
- 2 DOWN
- 3 UP
- 4 UP
- 5 UP
- 6 DOWN

These switch settings place the LaserWriter IINTX in:

PostScript Batch Mode,
RS-232 9600 Baud,
RS-422 9600 Baud,
7 data bits, No parity, 1 stop bit, with DTR/DSR handshake.

Step 3: Power On

Turn on the LaserWriter IINTX and the PC. After a few seconds, the LaserWriter IINTX will print a test page containing its current settings.

Step 4: PostScript Code

The PostScript code that follows is used to switch the LaserWriter IINTX into 8 data bit PostScript batch mode.

NOTE:

The "%" characters and following comments are not necessary, and can be omitted when typing in the program. Also, instances of control-z in parentheses mean hold down the control key and press z. The word "Return" in parentheses means to press your carriage return or enter key.

CAUTION:

If you choose to use the PostScript code provided in this article, you assume all risks involved in making these changes. PostScript code, if not entered correctly, can place the LaserWriter IINTX into a condition requiring service.

- For DTR/DSR, from the DOS prompt, type:

COPY CON POST.TXT

```
serverdict begin 0 exitserver %This exits the PostScript server loop
statusdict begin           %We're using an operator from statusdict
25 9600 68 setsccbatch      %set 25 pin port for 9600 Baud, 8, 1, DTR
end                         %Pop statusdict from the dictionary stack
(control-z) (Return)
```

- For XON/XOFF, from the DOS prompt, type:

COPY CON POST.TXT

```
serverdict begin 0 exitserver %This exits the PostScript server loop
statusdict begin           %Start modifying settings
25 9600 64 setsccbatch      %set 25 pin port for 9600 Baud, 8, 1, Xon/Xoff
end                         %Pop statusdict from the dictionary stack
(control-z) (Return)
```

Step 5: Batch File

A batch file needs to be created to set up the PCs communications port and to send the PostScript code to the printer. From the DOS prompt, type:

COPY CON POST.BAT

```
MODE COM1:96,N,8,1,P
MODE LPT1:=COM1
copy POST.TXT LPT1
(control-z) (Return)
```

Step 6: Change LaserWriter IINTX to 8 data bit PostScript batch mode

Type POST from the DOS prompt to set the NTX to 8 data bit PostScript batch mode. The printer will internally switch from the 7 data bit PostScript batch mode to 8 data bit PostScript batch mode.

Step 7: PostScript Code for testing the mode change

CAUTION:

If you choose to use the PostScript code provided in this article, you assume all risks involved in making these changes. PostScript code, if not entered correctly, can place the LaserWriter IINTX into a condition requiring service.

The PostScript code that follows tests the mode change. From the DOS prompt, type:

```
COPY CON TEST.TXT
/Helvetica findfont 14 scalefont setfont
72 720 moveto
(The Options number for the 25-pin port is:) show
statusdict begin 25 sccbatch 10 string cvs show
pop showpage
(control-z) (Return)
```

Step 8: Test mode change

To test the mode change, type the following from the DOS prompt:
COPY TEST.TXT LPT1

After a few seconds, the LaserWriter IINTX should print a page containing the following text:

'The Options number for the 25-pin port is xx'

Where 'xx' equals the third number in the third line of the PostScript code created in step 4 (either 68 or 64).

Problem Solving
=====

LaserWriter IINTX does not print after test PostScript code is sent:

Check cable connections and paper supply to the LaserWriter IINTX. Turn off any spooler commands that may be implemented on the PC. Check the PostScript files (POST.TXT) and (TEST.TXT) along with the (POST.BAT) batch file for any typing errors. If none are apparent, we suggest re-typing the code of both PostScript files from scratch.

If the LaserWriter IINTX does not receive the PostScript code character for character, the mode change or test will not work. Once the code has been re-typed, send it to the LaserWriter IINTX. If the LaserWriter IINTX prints the page, then all is well. If the LaserWriter IINTX does nothing, then start over from step 1.

LaserWriter IINTX will not print from within an application:

Check the applications print settings to ensure that it is sending output to LPT1 or COM1. The application must support PostScript, and must be set to output to a PostScript device.

Article Change History:

22 Aug 1995 - Made minor corrections.

09 Feb 1995 - Added PostScript caution and reformatted article.

LW IINTX In HP LaserJet+ Emulation Mode: Serial Connect From PC

Revised: 3/4/90
Security: Everyone

LW IINTX In HP LaserJet+ Emulation Mode: Serial Connect From PC

=====

This article last reviewed: 7 July 1988

Here are a few suggestions about printing to LaserWriter IINTX in LaserJet Plus emulation mode:

(NOTE: You may experience a communications problem printing in this configuration when the emulation mode is set by the DIP switches. The problem appears when printing the upper 127 ASCII characters and graphics, and is due to the serial port DIP setting of 7 data bits.)

Currently, there is no available method of software switching back to PostScript or any other emulation mode once leaving the PostScript mode. The correct method is to change the DIP switch settings and wait 30 seconds. If PostScript is desired, switch one should be set to DOWN. Wait 30 seconds and place switch back to the UP position.

To attain full emulation, the serial port can be configured as follows:

1) Connection:

Connect an Apple 25 pin Serial cable (590-0037) to an Apple Modem Eliminator (590-0166). Take one end and connect it to the 25 pin serial port on the LaserWriter IINTX. Connect the other end to a serial port on the PC.

(NOTE: Most serial ports for PCs use a male DB 25 connector. Since both ends of the Apple 25 pin serial cable are male, a female-to-female gender changer is required for connection to a PC serial port. An alternative is to use a straight pin-to-pin female-to-male DB 25 cable.)

2) Switch Settings:

While the LaserWriter IINTX is off, set the printers DIP switch settings to:

- 1 UP
- 2 DOWN

3 UP
4 UP
5 UP
6 DOWN

These switch settings place the LaserWriter IINTX in:

PostScript Batch Mode,
RS-232 9600 Baud,
RS-422 9600 Baud,
7 data bits, No parity check, 1 stop bit, with DTR/DSR handshake.

3) Power On:

Turn on the LaserWriter IINTX and the PC. After a few seconds the LaserWriter II will print a test page containing its current settings (listed above).

4) PostScript Code:

The PostScript code that follows is used to switch the LaserWriter II into LaserJet+ emulation mode.

(NOTE: The "%" characters and following comments are not necessary. Remove them when typing in the program.)

- For DTR/DSR, from the DOS prompt type:

```
COPY CON POST.TXT
serverdict begin 0 exitserver %This exits the printer server loop.
statusdict begin %Start modifying settings.
9 0 3 setsccbatch %Turns off the RS-422 9600 Baud port.
25 9600 68 setsccbatch %set the 25 pin RS-232 9600 Baud port-8 data
                        bits.
5 setsoftwareiomode %Set printer to HP LaserJet+ mode.
0 sethardwareiomode %Set communications mode to serial.
end %This is the end of the mode switch routine.
systemdict/quit get exec %Force an error to cause a system start test
                           page.
(control z) %The keyboard control key and the z key together.
              This ends text editing and saves the file.
```

- For XON/XOFF, from the DOS prompt type:

```
COPY CON POST.TXT
serverdict begin 0 exitserver %This exits the printer server loop.
statusdict begin %Start modifying settings.
9 0 3 setsccbatch %Turns off the RS-422 9600 Baud port.
25 9600 64 setsccbatch %set the 25 pin RS-232 9600 Baud port-8 data
                        bits.
5 setsoftwareiomode %Set printer to HP LaserJet+ mode.
0 sethardwareiomode %Set communications mode to serial.
end %This is the end of the mode switch routine.
```

```
systemdict/quit get exec      %Force an error to cause a system start test
                                page.
(control z)                   %The keyboard control key and the z key together.
                                This ends text editing and saves the file.
```

5) Batch File:

A batch file must be created to set up the PC's communications port, and to send the PostScript code to the printer.

From the DOS prompt type:

```
COPY CON HPMODE.BAT
MODE COM1:96,N,8,1,P
MODE LPT1:=COM1
TYPE POST.TXT > LPT1
(control z)
```

6) Change LaserWriter II to LaserJet+ emulation mode:

Type HPMODE from the DOS prompt to set the NTX to LaserJet+ emulation. The printer will internally switch from the PostScript Batch mode to LaserJet+ emulation, and after a few seconds it will print a test page displaying the new settings.

Your printer will now print graphics and text properly with the emulation provided by the Adobe PostScript ROMS. This fixes the problem of losing the 8th data bit for special text and graphics. This also fixes the problem of the "print screen" keyboard command not functioning.

Problem Solving:

LaserWriter II will not print test page to indicate HP emulation mode:

Check cable connections and paper supply to the LaserWriter II. Turn off any spooler commands that may be implemented on the PC.

Check the PostScript file (POST.TXT) and the batch file (HPMODE.BAT) for any typing errors. If none are apparent, try re-typing the PostScript code from scratch. If the LaserWriter II does not receive the PostScript code character for character, the mode change will not work.

Once the code has been re-typed, send it to the LaserWriter II. If the LaserWriter II prints a test page, then all is well. If the LaserWriter II prints out a page containing the PostScript code, it is in LaserJet+ emulation mode, but a test page will not be printed (there is an error in the PostScript code that instructs the LaserWriter II to print a test page, but the mode switch was successful). If the LaserWriter II does nothing, then start over from step 1.

LaserWriter II will not print from within an application:

Check the applications print settings to ensure that it is sending output to

LPT1 or COM1. The application also must be set up to print to a LaserJet+ using Times, Helvetica, or Courier.

NOTE: When printing from DOS, always follow the print command with a 'Control D'. A 'Control D' tells the LaserWriter II that the data transmission is completed and printing can now begin. The best method is to create another text file with a 'Control D' inside.

Enter the following from the DOS prompt-

```
COPY CON D.TXT
```

```
(Control D)
```

```
(Control Z) or (F6)
```

Now, you make a batch file to send the end of page marker to the printer.

From the DOS prompt enter-

```
COPY CON END.BAT
```

```
TYPE D.TXT > LPT1
```

```
(Control Z) or (F6)
```

After doing a TYPE or Print Screen or DIR to the printer, just type END, and the printer will print any remaining data in the buffer.

If your print job does not have a Control-D (end of page) character, you will have to wait for your print job until a time-out, or until another job is printed that is larger than a page.

LaserWriter IINT: Serial PostScript Batch Mode From DOS (8/95)

Revised: 8/23/95
Security: Everyone

LaserWriter IINT: Serial PostScript Batch Mode From DOS (8/95)

=====

Article Created: 7 July 1988
Article Reviewed/Updated: 22 August 1995

TOPIC -----

If you need to print with LaserWriter IINT in PostScript batch mode, here is the method for serial connection from a PC.

DISCUSSION -----

Step 1

Connection:

Connect a 25-pin Serial cable from the LaserWriter IINT to the serial port on the MS-DOS PC.

Step 2

Switch Settings:

While the LaserWriter IINT is off, set the printers DIP switch settings to:

- 1 UP
- 2 DOWN

These switch settings place the LaserWriter IINT in:

PostScript Batch Mode,
RS-232 9600 Baud,
RS-422 9600 Baud,
7 data bits, No parity check, 1 stop bit, with XON/XOFF handshake.

Step 3

Power On:

Turn on the LaserWriter IINTX and the PC. After a few seconds the LaserWriter IINT will print a test page containing its current settings (listed above).

Step 4

PostScript Code:

The PostScript code that follows is used to switch the LaserWriter IINT into 8 data bit PostScript batch mode.

Caution:

If you choose to use the PostScript code provided in this article, you assume all risks involved in making these changes. PostScript code, if not entered correctly, can place the LaserWriter IINT into a condition requiring service.

NOTE:

The "%" characters and following comments are not necessary. Remove them when typing in the program.

- For DTR/DSR, from the DOS prompt type:

COPY CON POST.TXT

%=====

% Begin PostScript Code

%

serverdict begin 0 exitserver %This exits the printer server loop.

statusdict begin %Start modifying settings.

25 9600 68 setsccbatch %set the 25 pin RS-232 9600 Baud port-8 data bits.

% end %This is the end of the mode switch routine.

(control z) %The keyboard control key and the z key together. This ends text editing and saves the file.

% End PostScript Code

%=====

- For XON/XOFF, from the DOS prompt type:

COPY CON POST.TXT

%=====

% Begin PostScript Code

%

serverdict begin 0 exitserver %This exits the printer server loop

statusdict begin %Start modifying settings

25 9600 64 setsccbatch %set the 25 pin RS-232 9600 Baud port-8 data bits

% end %This is the end of the mode switch routine

(control z) %The keyboard control key and the z key together. This ends text editing and saves the file.

%

```
% End PostScript Code
```

```
%=====
```

Step 5

Batch File:

A batch file must be created to set up the PC's communications port, and to send the PostScript code to the printer. From the DOS prompt type:

```
COPY CON POST.BAT
MODE COM1:96,N,8,1,P
MODE LPT1:=COM1
TYPE POST.TXT > LPT1
(control z)
```

Step 6

Change LaserWriter IINT to 8 data bit PostScript batch mode:

Type POST from the DOS prompt to set the NT to 8 data bit PostScript batch mode. The printer will switch internally from the 7 data bit PostScript batch mode to 8 data bit PostScript batch mode.

Step 7

PostScript Code for testing the mode change:

The PostScript code that follows tests the mode change. From the DOS prompt type:

```
COPY CON TEST.TXT
%=====
% Begin PostScript Code
%
/Helvetica findfont 14 scalefont setfont
30 500 moveto
(The Options number for the 25-pin port is:)
show statusdict begin 25 sccbatch 10 string cvs show
pop showpage
(control z)
%
% End PostScript Code
%=====
```

Step 8

Test mode change:

To test the mode change, type the following from the DOS prompt:

```
TYPE TEST.TXT > LPT1
```

After a few seconds, the LaserWriter IINT should print a page containing the

following text:

'The Options number for the 25-pin port is xx'

Where 'xx' equals the third number in the third line of the PostScript code created in step 4 (either 68 or 64).

NOTE:

The LaserWriter IINT does not support software switching between configurations. For example, PostScript and Diablo or LocalTalk and serial.

Problem Solving:
=====

LaserWriter IINT does not print after test PostScript code is sent:

Check cable connections and paper supply to the LaserWriter IINT. Turn off any spooler commands that may be implemented on the PC.

Check the PostScript files (POST.TXT) and (TEST.TXT) along with the (POST.BAT) batch file for any typing errors. If none are apparent, we suggest re-typing the code of both PostScript files from scratch. If the LaserWriter IINT does not receive the PostScript code character for character, the mode change or test will not work. If you have the ability to copy and paste the PostScript Code into a text file, you should do this instead.

Once the code has been re-typed, send it to the LaserWriter IINT. If the LaserWriter IINT prints the page, then all is well. If the LaserWriter IINT does nothing, then start over from step 1.

LaserWriter IINT will not print from within an application:

Check the applications print settings to ensure that it is sending output to LPT1 or COM1. The application must support PostScript, and must be set to output to a PostScript device.

Article Change History:

22 Aug 1995 - Made minor corrections.

21 Feb 1995 - Reformatted and added PostScript caution.

EtherTalk Speeds Up MultiUser AppleShare Application

Revised: 12/6/89
Security: Everyone

EtherTalk Speeds Up MultiUser AppleShare Application

=====

This article last reviewed: 29 June 1988

Here are the results of some tests performed on the EtherTalk card and the AppleTalk card. They suggest some speed advantages using the EtherTalk card in a multiuser AppleShare application.

Some Hints:

The EtherTalk boards come preset for thick-wire EtherNet. To change them to thin-wire it is necessary to move a jumper on the board. This procedure is well documented in the EtherTalk Interface Card manual.

It is also mandatory that the cable itself be terminated on both ends. Terminators must fit on the open end of the T-connection on each card. (The testing group took one from their FastPath for these explorations.)

Also, the EtherTalk software must be installed into the system via Installer, so that it shows up in the Control Panel as a Network icon on the left, which -- when selected -- allows you to choose the built-in port or the EtherTalk card. If you are connected to two networks, one AppleTalk and one EtherTalk, you can toggle back and forth with the Network icon in the Control Panel. This is not a gateway from one to the other, just a means of switching back and forth.

The Benchmarks:

As part of the test, some benchmarks were performed which are documented below. The numbers are representative of the differences, but will change according to configurations, number of users, and the application being run.

- For one benchmark, Excel was opened on the server from the workstation in both modes: EtherTalk and AppleTalk. The AppleTalk time was roughly 30 seconds; the EtherTalk time roughly 19 seconds -- approximately 37% faster.
- Another test was running HyperCard from the server itself. EtherTalk seemed

to be at least 95% as fast at showing all cards in the address stack as HyperCard would be from a local hard disk.

Finally, the most comprehensive benchmarks. Two sets of tests were run, called Configuration A and Configuration B.

Configuration A:

- These were done on a Macintosh Plus-based system with a 4MB Macintosh Plus as the AppleShare server, and a 2MB Macintosh Plus as the workstation. RAM cache on the server was automatically set by AppleShare v1.1 at 32k.

(NOTE: Larger RAM cache settings actually slowed down the response times!)

The workstation was operating from a single floppy containing Finder 6.0b2 and System 4.1. The application 4th Dimension (runtime version) was running off the file server, since there wasn't room for the application on the floppy containing System and Finder. 4th Dimension was running in multi-user mode with one user. The network was AppleTalk, both cable and protocol. The server used an Apple 40SC drive.

Configuration B:

- Tests were done on a Macintosh II based system with a 5mb Macintosh II as the workstation and a 1mb Macintosh II as the server. Both Macintoshes were connected using EtherTalk. The server disk was the same Apple 40SC as in Configuration A. Again, the tests were done with the workstation using a floppy-based System v4.1 and Finder v6.0b2. RAM cache settings were not recorded. 4th Dimension was running in multi-user mode with one user off the server volume.

The time tests involved two parts: timing the launch of the data base, then timing a series of typical operations. These operations typically involved reading and/or writing data, and the reading of screen layouts (mostly dialogs).

The Results:

TEST	CONF. A (seconds)	CONF. B (seconds)	% DIFFERENCE
----	-----	-----	-----
Launch	359	124	35%
Oper.1	12	5	42%
Oper.2	26	10	38%
Oper.3	15	6	40%
Oper.4	28	11	39%
Oper.5	18	6	33%

Oper.6

35

12

34%

It appears from these tests that the Macintosh II in combination with EtherTalk is two or three times faster than the Macintosh Plus with LocalTalk cabling.

LaserWriter Documents Sent To Off-Line Printer Won't Re-direct

Revised: 7/14/88
Security: Everyone

LaserWriter Documents Sent To Off-Line Printer Won't Re-direct

=====

This article last reviewed: 28 June 1988

LaserWriters using Print Monitor have a problem when they spool to a printer that is no longer connected to the network, but is still named in the Chooser.

Spooled files may only be printed by Print Monitor, and only to a LaserWriter with the same name as selected in Chooser at the time the document was spooled. If a file is spooled to a printer that is no longer attached to the network, it can't be re-directed. You must instead tell the Print Monitor to "wait until later", or cancel the job outright.

The only current workaround is to use the Namer to re-name a printer attached to the network, then change its name back after the job has been printed.

Macintosh System Software 6.0 Compatibility Report (3 of 3) 3/93

Article Created: 14 July 1988

Article Change History

03/15/93 - UPDATED
• Acius now ACI US, Inc.

This article continued from: "Macintosh System Software 6.0 Compatibility Report (Part 2 of 3)".

System Software 6.0 Compatibility Report as of 6/20/88

The following applications have been rated with a 'C' status. C = The application is now having minor loss of functionality running under System Software 6.0.

Product	CPU	Company
Color More 1.1c	Mac II	Living VideoText

Invisible files created by Color More 1.1c are visible and openable from the desktop. Color More 1.1c also rated a "C" with System 5.0.

Frame Mac 1.10	Mac II	Compuneering
----------------	--------	--------------

Documents must be opened from within the application. Frame Mac 1.10 also rated a "C" with System 5.0.

Guide 1.0	ALL	Owl, Int.
-----------	-----	-----------

Unable to print to LaserWriter and/or ImageWriter. No work-around known. Guide 1.0 also rated a "C" with System 5.0

Mac Cogo 1.01	ALL	Compuneering
Problem with the circle tool at 200% page resolution. Mac Cogo 1.01 is not compatible with MacroMaker. Mac Cogo 1.01 also rated a "C" with System 5.0.		
Works 1.1	ALL	Microsoft
Works 1.1 is not compatible with MultiFinder, use single Finder until you receive Microsoft's planned patch.		
McNet 2.12	ALL	Argus Software
Screen refresh problems with 2.12. You are only able to switch layers under MultiFinder while in Drawing mode. McNet 2.12 also rated a "C" with System 5.0.		
MGMStation 2.09	Mac II	Micro CAD/CAM
Numerous screen refresh problems. Small problems with application errors. Overall rating of MGMStation 2.09 has not changed from 5.0 to 6.0.		
Omnis 3+ 3.24	ALL	Blyth
You should increase default memory size in "Get Info" Box on Mac IIs. Avoid using "Go To Utilities" in the "Options" menu. Omnis 3+ 3.24 also rated a "C" with System 5.0.		
PageMaker 2.0a	ALL	Aldus
Avoid using MacroMaker with PageMaker 2.0a. PageMaker 2.0a also rated a "C" with System 5.0.		
Trapeze 2.0	Mac+,SE	Data Tailor
No new problems introduced with 6.0 on the Plus or SE. Trapeze 2.0 also rated a "C" with System 5.0 on the Plus and SE.		
VideoWorks II 2.0	ALL	Broderbund
VideoWorks II 2.0 draws over active windows under MultiFinder. VideoWorks II 2.0 also rated a "C" with System 5.0.		
Microsoft File 1.05	ALL	Microsoft
"Page Setup" is not displayed after selecting another printer with Chooser. File also has some screen refresh problems after using DAs.		
WriteNow 1.07	ALL	Ann Arbor
Cut & Paste is not fully reliable. Margin problems when printing in 2 column.		

The following applications have been rated with a 'D' status. D = The application is experiencing major loss of functionality and is not compatible with System Software 6.0.

Product	CPU	Company
DBase Mac 1.0	ALL	Borland International

With the exception of an incompatibility with MacroMaker, no other problems were introduced with 6.0

MacDraft 1.2a	ALL	
---------------	-----	--

Due to numerous compatibility problems, do not use MacDraft 1.2a with 6.0.

MacTex 2.0	ALL	STL Systems
------------	-----	-------------

System hangs as you attempt to launch on Mac SE or II. Numerous crashes on the Plus. MacTex also rated a "D" with System 5.0.

ResEdit 1.1b3	ALL	
---------------	-----	--

Due to numerous compatibility problems, do not use ResEdit 1.1b3 with 6.0. ResEdit 1.1b3 also rated a "D" with System 5.0.

Trapeze 2.0	Mac II	Data Tailor
-------------	--------	-------------

Due to numerous compatibility problems, do not use ResEdit Trapeze 2.0 with 6.0 on a Mac II. Trapeze 2.0 also rated a "D" with System 5.0 on the Mac II.

4th Dimension 1.0.4	ALL	ACI US, Inc.
---------------------	-----	--------------

4D crashes as you enter the 4D Layout Editor.4D rated a "C" with System 5.0.

Insight General Ledger 2.0	ALL	Layered
----------------------------	-----	---------

Insight General Ledger 2.0 is not able to print. Avoid using the "Change Company" option under "File". Insight General Ledger 2.0 had been rated as a "C" with System 5.0

Excel 1.04	ALL	Microsoft
------------	-----	-----------

System crash as you open an Excel document if MacroMaker was launched at start-up. Excel users should be using Excel 1.06 or 1.5 with System 6.0.

This concludes "Macintosh System Software 6.0 Compatibility Report"

APPLE III: Keyboard Replacement

Revised: 7/17/92
Security: Everyone

APPLE III: Keyboard Replacement

=====

Article Created: 12 July 1988
Article Last Reviewed: 17 July 1992
Article Last Updated:

The Apple III keyboard (P/N 661-91022) is no longer available as a replacement module. If you order an Apple III keyboard, you will receive an Apple III Plus keyboard, keyboard cover, and keyboard encoder ROM. To replace a defective Apple III keyboard, exchange the old Apple III keyboard, keyboard cover, and keyboard encoder ROM with the new Apple III Plus keyboard, keyboard cover, and keyboard encoder ROM.

BEFORE YOU START: Familiarize yourself with the Apple III Technical Procedures. Be sure to follow proper ESD procedures.

Materials Required:

- Grounded workbench and wriststrap
- Medium flatblade screwdriver
- Small phillips screwdriver
- Medium phillips screwdriver
- IC extractor
- Keyboard encoder ROM P/N 342-0136 (included with new keyboard)
- Apple III Plus keyboard (included with new keyboard)
- Apple III Plus keyboard cover (included with new keyboard)

Replacement Procedure: To replace the Apple III keyboard:

1. Power off the Apple III and disconnect the AC power cord.
2. Disconnect all other external cables from the back of the Apple III.
3. Remove the main logic assembly (refer to Section 2, Take-Apart, of the Apple III and Apple III Plus Technical Procedures).

4. Place the main logic board on a grounded workbench pad and put on your grounding wriststrap.
5. Locate the keyboard encoder ROM at coordinate J13 on the main logic board and verify that it is the old ROM (P/N 341-0035).
6. Using an IC extractor, remove the old ROM at location J13.
7. Install the new keyboard encoder ROM (P/N 342-0136) at the same location, J13 on the main logic board. There is a small notch on the ROM. This notch should face away from the output connectors.
8. Replace the main logic assembly (refer to Section 2, Take-Apart, of the Apple III and Apple III Plus Technical Procedures).
9. Remove the keyboard and keyboard cover (refer to Section 2, Take-Apart, of the Apple III and Apple III Plus Technical Procedures).
10. Install the Apple III Plus keyboard and keyboard cover (refer to Section 2, Take-Apart, of the Apple III and Apple III Plus Technical Procedures).

Hard Disk 20: Hard Drive Diagnostic 4.0 Problem/Cure

Revised: 7/22/88
Security: Everyone

Hard Disk 20: Hard Drive Diagnostic 4.0 Problem/Cure

=====

This article last reviewed: 8 July 1988

PROBLEM: When testing a Hard Disk 20 (i.e. non SCSI hard disk) on a Macintosh SE, the test will always fail a Hard Disk 20, even if the Hard Disk 20 is a known good unit.

CURE: This problem with Hard Disk Drive Diagnostic 4.0 is caused by a bug in the software which will cause it to falsely fail a non-SCSI Hard Disk 20 when tested on a Macintosh SE. The solution is to test the Hard Disk 20 ONLY on a Macintosh Plus.

PROBLEM: If the Hard Disk 20 was formatted on a Macintosh SE, the HD20 still fails MacTest Drive Diagnostics 4.0 on the Macintosh Plus.

CURE: Format the Hard Disk 20 on the Macintosh Plus and test the drive again.

ImageWriter & Dot Matrix Printer: Stops Printing Problem/Cure

Revised: 7/22/88
Security: Everyone

ImageWriter & Dot Matrix Printer: Stops Printing Problem/Cure

=====

This article last reviewed: 13 July 1988

Problem:

Symptom #1: During printing the Dot Matrix Printer or Imagewriter may halt printing for no apparent reason and the select light will go out. Restarting the printer or pressing the select button seems to correct the problem temporarily.

Symptom #2: During power up the carriage assembly moves to the far left position as in the normal power on sequence, but the carriage assembly then fails to make its characteristic 3/4" movement to the right and then back to the left position. In addition, the 'select' light fails to appear. Powering off and on the printer repeatedly fails to produce the results above unless the carriage assembly is moved to somewhere other than the far left position. Instead, the platen will advance and retract approximately 1/4", and the carriage assembly will move approx. 1/16" and halt.

Cure:

Replace the right margin disable switch which is available for the Imagewriter as part # 970-0715 (Power Switch/Control Panel Cable Assembly). For the DMP the switch itself needs to be removed and a replacement keyswitch (705-0079) needs to be used since the complete assembly is no longer available for the DMP.

LaserWriter: LaserJet Plus Emulation Over AppleTalk

Revised: 9/10/92
Security: Everyone

LaserWriter: LaserJet Plus Emulation Over AppleTalk

=====

Article Created: 12 July 1988

Article Change History

08/20/92 - UPDATED

- To include Personal LaserWriter NT and NTR.

TOPIC -----

How can I print from a PC with the LaserWriter IINTX or Personal LaserWriter NT or NTR in HP LaserJet Plus emulation mode over AppleTalk (that is, with an AppleTalk card in the PC)?

DISCUSSION -----

Here are the steps you need to follow. The article concludes with two troubleshooting sections:

Step One: Connection

1) Connect a LocalTalk connector box to the appropriate port on the PC. (An AppleTalk interface card must be installed inside the PC.)

2) Connect another LocalTalk connector box to the LaserWriter.

3) Using a LocalTalk cable, connect the two connector boxes together.

(Note: If more devices are to be added to the AppleTalk network, consult the manual that came with your LocalTalk cables and connectors.)

Step Two: Switch Settings

While the LaserWriter is off, set the printer switches according to the

following list.

These switch settings place the LaserWriter IINTX in PostScript Batch Mode, AppleTalk:

- 1 UP
- 2 UP
- 3 UP
- 4 UP
- 5 UP (any position)
- 6 UP (any position)

To place the Personal LaserWriter NT in PostScript Batch Mode, AppleTalk, set the single pushwheel switch to either position "0" or "7."

Step Three: Power On

Turn on the LaserWriter and the PC. After a few seconds, the LaserWriter prints a test page containing its current settings.

Step Four: Change LaserWriter to LaserJet Plus Emulation Mode

The following PostScript code switches the LaserWriter into LaserJet Plus emulation mode. Note: The "%" characters and following comments are not necessary. You can omit them when typing in the program. From the DOS prompt, type the following:

```
COPY CON POST.TXT
serverdict begin 0 exitserver %This exits the printer server loop.
statusdict begin           %Start modifying settings.
5 setsoftwareiomode        %Set printer to HP LaserJet+ mode.
end                         %This is the end of the mode switch routine.
systemdict/quit get exec   %Force an error to cause a system start test
                           %page.
(control z)                %Press the keyboard control key and the z key
                           %together. This ends text editing and saves
                           %the file.
```

Step Five: PostScript Code

Send the PostScript file through a PostScript download utility (included with most AppleTalk interface cards for the PC) or an application like Microsoft Word (which contains PostScript code printing). Once the file has been sent, the printer switches internally from the PostScript batch mode to LaserJet Plus emulation. After a few seconds, it prints a test page displaying the new settings.

Note: Currently, there is no method of software switching back to PostScript or to any other emulation mode once you have left PostScript mode on the LaserWriter. The correct method is to change the DIP switch settings and wait 30 seconds. If you want to use PostScript, switch one should be set to DOWN. Wait 30 seconds and move the switch back to the UP position.

Troubleshooting: No test page

If the LaserWriter will not print a test page to indicate HP emulation mode, follow these steps:

- 1) Check cable, connector box connections, and paper supply to the LaserWriter.
- 2) Turn off any spooler commands that may be implemented on the PC.
- 3) Check the PostScript file (POST.TXT) for any typing errors. If none are apparent, we suggest re-typing the PostScript code from scratch. If the LaserWriter II does not get the PostScript code character for character, the mode change will not work.
- 4) Once the code has been retyped, send it to the LaserWriter. If the LaserWriter prints a test page, then all is well. If the LaserWriter prints out a page containing the PostScript code, it is in LaserJet+ emulation mode, but a test page will not be printed. (There is an error in the PostScript code that instructs the LaserWriter IINTX to print a test page, but the mode switch was successful.)
- 5) If the LaserWriter does nothing, then start over from step 1.

Troubleshooting: No printing from within an application

If the LaserWriter won't print from within an application, check these things:

- The application must also be set up to print to a LaserJet+ using Times, Helvetica, or Courier.
- The application must be capable of sending output over an AppleTalk network.

LW IINTX: Diablo 630 Emulation Mode

Revised: 1/7/92
Security: Everyone

LW IINTX: Diablo 630 Emulation Mode

=====

Article Created: 12 July 1988
Article Last Reviewed: 29 May 1991
Article Last Updated:

TOPIC -----

If you want to print from a PC to a LaserWriter IINTX set in Diablo 630 emulation mode, this article contains some suggestions.

DISCUSSION -----

Preliminary Note: You may experience a problem printing to the LaserWriter IINTX in Diablo mode when the emulation mode is set by the DIP switches. A communication problem appears when printing the upper 127 ASCII characters. The problem is related to the serial port DIP setting of 7 data bits. To attain full emulation, the serial port can be configured detailed in this article.

Currently, there is no method of software switching back to PostScript or to any other emulation mode once you have left the PostScript mode. The correct method is to change the DIP switch settings and wait 30 seconds. If you want to use PostScript, switch one should be set to DOWN. Wait 30 seconds and move the switch back to the UP position.

Step One: Connection

Connect an Apple 25-pin Serial cable (590-0037) to an Apple Modem Eliminator (590-0166). Take one end and connect it to the 25-pin serial port on the LaserWriter IINTX. Connect the other end to a serial port on the PC.

Note: Most serial ports for PCs use a male DB-25 connector. Because both ends of the Apple 25-pin serial cable are male, you need a female-to-female "gender mender" to connect to a PC serial port. Alternatively, you can use a straight, pin-to-pin, female-to-male, DB-25 cable.

Step Two: Switch Settings

While the LaserWriter IINTX is off, set these printer DIP switch settings:

- 1 UP
- 2 DOWN
- 3 UP
- 4 UP
- 5 UP
- 6 DOWN

These switch settings place the LaserWriter IINTX in:

- PostScript Batch Mode,
- RS-232 9600 Baud
- RS-422 9600 Baud
- 7 data bits, No parity check, 1 stop bit, with DTR/DSR handshake

Step Three: Power On

Turn on the LaserWriter IINTX and the PC. After a few seconds, the LaserWriter IINTX prints a test page containing its current settings (listed above).

Step Four: PostScript Code

The following PostScript code switches the LaserWriter II into LaserJet+ emulation mode. Note: The "%" characters and following comments are not necessary. You can omit them when typing in the program. For DTR/DSR, from the DOS prompt type:

```
COPY CON POST.TXT
serverdict begin 0 exitserver %This exits the printer server loop.
statusdict begin           %Start modifying stuff.
9 0 3 setsccbatch          %Turns off the RS-422 9600 Baud port.
25 9600 68 setsccbatch     %set the 25 pin RS-232 9600 Baud port-8 data
                           bits.
2 setsoftwareiomode        %Set printer to Diablo 630 emulation mode.
0 sethardwareiomode        %Set communications mode to serial.
end                        %This is the end of the mode switch routine.
systemdict/quit get exec   %Set the printer up for a fall.
30 400 moveto              %Force an error to cause a system start test
                           %page.
(control z)                %The keyboard control key and the z key
                           %together. This ends text editing and saves
                           %the file.
```

For XON/XOFF, from the DOS prompt type:

```
COPY CON POST.TXT
serverdict begin 0 exitserver %This exits the printer server loop.
statusdict begin           %Start modifying stuff.
9 0 3 setsccbatch          %Turns off the RS-422 9600 Baud port.
```

```
25 9600 64 setscbatch      %set the 25 pin RS-232 9600 Baud port-8 data
                           %bits.
2 setsoftwareiomode       %Set printer to Diablo 630 emulation mode.
0 sethardwareiomode       %Set communications mode to serial.
end                       %This is the end of the mode switch routine.
systemdict/quit get exec  %Set the printer up for a fall.
30 400 moveto             %Force an error to cause a system start test
                           %page.
(control z)               %The keyboard control key and the z key
                           %together. This ends text editing and saves
                           %the file.
```

Step Five: Batch File

You need to create a batch file to set up the PC's communications port and to send the PostScript code to the printer.

1) From the DOS prompt, type:

```
COPY CON DIABLO.BAT
MODE COM1:96,N,8,1,P
MODE LPT1:=COM1
TYPE POST.TXT > LPT1
```

2) Press Control-Z to conclude.

Step Six: Change LaserWriter IINTX to Diablo 630 Emulation Mode

Type DIABLO from the DOS prompt to set the NTX to Diablo emulation. The printer switches internally from the PostScript Batch mode to Diablo 630 emulation. After a few seconds, it prints a test page displaying the new settings.

Your printer will now print graphics and text properly with the emulation provided by the Adobe PostScript ROMS. This solves the problem of losing the 8th data bit for special text and graphics, as well as the problem with the "print screen" keyboard command not functioning.

Troubleshooting: No test page

The LaserWriter IINTX will not print a test page to indicate Diablo emulation mode, follow these steps:

- 1) Check cable, connector box connections, and paper supply to the LaserWriter II.
- 2) Turn off any spooler commands that may be implemented on the PC.
- 3) Check the PostScript file (POST.TXT) and the batch file (DIABLO.BAT) for any typing errors. If none is apparent, we suggest re-typing the PostScript code from scratch. If the LaserWriter II does not get the PostScript code character-for-character, the mode change will not work.

- 4) Once the code has been retyped, send it to the LaserWriter IINTX. If the LaserWriter IINTX prints a test page, then all is well. If the LaserWriter IINTX prints out a page containing the PostScript code, it is in Diablo emulation mode, but a test page will not be printed. (There is an error in the PostScript code that instructs the LaserWriter IINTX to print a test page, but the mode switch was successful.)
- 5) If the LaserWriter II does nothing, then start over from step 1.

Troubleshooting: Not printing from an application

If the LaserWriter IINTX will not print from within an application, do these steps:

- 1) Check the applications print settings to ensure that it is sending output to LPT1 or COM1.

(Note: When printing from DOS, always follow the print command with a "Control D." A "Control D" tells the LaserWriter IINTX that the data transmission is completed and printing can now begin. The best method is to create another text file with a "Control D" inside.

Enter the following from the DOS prompt:

```
COPY CON D.TXT
(Control D)
(Control Z) or (F6)
```

Now, make a batch file to send the end-of-page marker to the printer.

From the DOS prompt, enter:

```
COPY CON END.BAT
TYPE D.TXT > LPT1
(Control Z) or (F6)
```

After doing a TYPE or Print Screen or DIR to the printer, just type END, and the printer will print any remaining data in the buffer.

If your print job does not have a Control-D (end of page) character, you will have to wait for a job time-out for your print job or until another job (that is longer than a page) is printed.

ImageWriter LQ & A4: Workaround To Paper Length Problem

Revised: 8/1/88
Security: Everyone

ImageWriter LQ & A4: Workaround To Paper Length Problem

=====

This article last reviewed: 12 July 1988

An ImageWriter LQ has a DIP switch that configures the form length of continuous paper at 11 or 12 inches. A4 is 11.69 inches. When printing from the driver with A4 and continuous paper selected, the perforation position changes -- for obvious reasons.

Changing the position of switch 1-4 (Page Length) makes no difference in the page length when printing from a Macintosh. The page length remains 11 inches whether switch 1-4 is in the ON or OFF position.

To correct this problem, change the position of switch 1-5 (Perforation Skip), then select A4 page length and continuous paper, and print.

Printing Envelopes With the LaserWriter II

Revised: 8/1/88
Security: Everyone

Printing Envelopes With the LaserWriter II

=====

This article last reviewed: 12 July 1988

Here are the answers to some commonly asked questions about printing envelopes on the LaserWriter II, including:

- Which printer driver supports the envelope sheet feeder for the LaserWriter II family?
- What paper size must be chosen in the Page Setup menu?
- Can a custom paper size be used?

There is no need to specify paper sizes when printing envelopes on the LaserWriter II.

Tests done with Microsoft Works (v1.1), Microsoft Word (v3.01), and MacWrite (v4.6) showed differences in the address block locations when printed from these applications. However, most were correctable within a couple of tries.

Printing parameters used for all three applications:

Left Margin	3.5"
Carriage Returns from Top	12
Courier Font	14-point

The results:

	Distance from Left Edge of Envelope	Distance from Top of Envelope
Microsoft Works	4-5/16"	1-9/16"
Microsoft Word	4-5/16"	1-3/8"
MacWrite 4.6	3-7/8"	1"

..TIL03106-Printing_Envelopes_With_the_LaserWriter_II_(TA38884).pdf

As a workaround, save the print parameters for envelopes in a file, and use this file only to print to envelopes.

The LaserWriter IINT/NTX manual specifications state: "Type the address block with an upper margin of approximately 1.5 inches and a left margin that centers it on the screen." Use this as a starting point for final placement.

LaserWriter IINTX: Calculating Font Caching RAM

Revised: 9/22/89
Security: Everyone

LaserWriter IINTX: Calculating Font Caching RAM

=====

This article last reviewed: 12 July 1988

Some users who want to use multiple font families have asked if there is a way to estimate or calculate the increase in font cache size to allow more font families in the cache.

This is to enable the user to find the minimum amount of RAM to add to the LaserWriter IINTX that will allow the use of several font families without having to download the font per print request.

Font cache and display list sizes are persistent parameters and can be reset.

The default values (in hex) are:

	2MB or less	3MB or less	3MB or more
Font Cache size	\$28600	\$33000	10% RAM size
Display List size	\$10000	\$15000	10% RAM size

These parameters allow setting the RAM allocation in the LaserWriter IINTX. HOWEVER, if used incorrectly, they could have DISASTROUS effects on the operation of the printer. (Normally these values are set to 0 in the EEROM (ZPRAM), which tells the printer to calculate the necessary sizes based on RAM size.)

As determined from the above information, if the LaserWriter has 3MB or more RAM installed, the printer allocates 10% to font cache. If you know the amount of space each font family occupies, you can determine the amount of memory available for font caching.

Or, a hard disk can be attached to the LaserWriter IINTX, which would have more than enough space for a group of font families.

System 5.0 PrintMonitor & LW Drivers: Use Install Method

Revised: 11/4/91
Security: Everyone

System 5.0 PrintMonitor & LW Drivers: Use "Install" Method

=====

Article Created: 1 August 1988
Article Last Reviewed: 4 November 1991
Article Last Updated: 3 May 1989

TOPIC -----

This articles describes using PrintMonitor with System Software 5.0

DISCUSSION -----

Some Macintosh users, running System 5.0, have discovered that background printing can't be selected in the Chooser.

This situation is probably due to the PrintMonitor and LaserWriter drivers having been installed using the "drag" method.

With System Software 5.0, it is necessary to use the "Background LaserWriter (5.0)" installer script on System Tools Disk #2 to use background printing. After installation is complete you must select a LaserWriter as the print device; then the Background Printing option becomes available in the Chooser window.

(NOTE: This procedure is NOT necessary with System Software 6.0.)

LaserWriter IINTX: Does Not Support 6MB Configuration

=====

Article Created: 13 July 1988
Article Last Reviewed: 28 March 1991
Article Last Updated: 28 March 1991

TOPIC -----

Can you upgrade the LaserWriter IINTX memory to 6MB of RAM?

DISCUSSION -----

Specified memory configurations for the LaserWriter IINTX include 2, 3, 4, 5, 8, 9, and 12MB RAM.

The 6MB configuration is not supported by the LaserWriter IINTX hardware and firmware. It is physically possible to plug 6MB into the printer, but the printer will not recognize the extra memory.

AppleShare 1.1 & Srvr 2.0 Limit: Maximum Of 16 Volumes (11/94)

=====

Article Created: 13 July 1988
Article Reviewed/Updated: 21 November 1994

TOPIC -----

Some users are operating large databanks as an AppleShare server. When you create more than 16 partitions on their databank, you will find that only 16 of those partitions appear upon accessing AppleShare (V1.1, File Server v2.0).

DISCUSSION -----

The reason for this has remained undocumented so far, and there has been some confusion as to whether this is a Finder problem or an AppleShare problem.

AppleShare v1.1 and AppleShare File Server v2.0 provide access to a MAXIMUM of 16 server volumes. It is NOT a Finder limitation; there is no way around this limit.

ImageWriter LQ: Matching ImageWriter II Font Sizes

=====

This article last reviewed: 14 July 1988

Some customers using ImageWriter II to fill in forms from a database application find that when they switch to ImageWriter LQ -- using the same fonts and sizes as with ImageWriter II -- the printouts no longer fit the forms.

Such a problem may be due the print quality -- "Draft", "Faster", or "Best" -- used with the application.

When the application in use makes a Font Manager call to print text, the Font Manager asks the printer driver for a scaling call to relate the printer font to the screen font.

When "Faster" quality printing is requested, the ImageWriter LQ printer driver returns a scaling factor of 1:1 (both horizontal and vertical). The Font Manager then selects the exact same font as on the screen and sends it for printing.

The ImageWriter LQ printer driver sets the ImageWriter LQ to standard resolution graphics mode, turns on boldface printing, and sends the text to the printer as graphics data. (Boldface printing is used to print in "Faster" mode because the print density would be too light at the standard-resolution vertical dot spacing of 72 dpi.)

If "Best" quality printing is used, the Font Manager finds a font to use. If there is no 3X font installed in the system, the Font Manager uses:

1. A font twice the size desired, or:
2. A font half the size desired, or:
3. The next larger font it can find, or:
4. The next smaller font it can find.

If there is no screen font for the selected font family, the Font Manager uses a default application font. If there is no default application font, the Font

Manager uses a default system font.

Also, the ImageWriter LQ, even in draft mode, has a minimum character width of 12 dots with a normal size of 16 dots, while the ImageWriter II has a MAXIMUM character width of 7 dots with a normal size of 5 dots. This is why the fonts are closer in size to the LaserWriter than the ImageWriter.

A possible workaround is to remove any font size larger than the size being printed, which forces the Font Manager to use the next smaller size it finds. The Font Manager may scale the smaller font to an appropriate size for printing from 4th Dimension.

Further information on Macintosh fonts for the ImageWriter LQ begins on page 215 of Appendix D in the ImageWriter LQ Reference manual from Addison-Wesley (ISBN 0-201-17751-X).

ImageWriter II: Makes Buzzing Noise And Left Margin Changes

Revised: 8/2/88
Security: Everyone

ImageWriter II: Makes Buzzing Noise And Left Margin Changes

=====

This article last reviewed: 18 July 1988

PROBLEM:

During printing, the ImageWriter II carriage assembly may intermittently halt its movement and the carriage motor momentarily makes a high pitched buzzing noise. If the printer does resume its printing then the left margin will have changed and the carriage assembly will probably have moved to the right, forcing the carriage to slam into the right side of the frame.

IDENTIFYING THE PROBLEM:

Turn the power off on the printer and remove the top cover. Slowly move the carriage assembly back and forth across the full length of the carriage and watch the metal paper deflector for any slight movement of 1/16th of an inch or less. If movement is present, it indicates that the paper guide is rubbing on the paper deflector.

CURE:

This problem occurs when the paper guide has been improperly adjusted, and the paper thickness lever is in its full forward position. It can also occur if the paper deflector (076-0008) is defective.

In order to correct this problem try reinstalling the paper guide according to the procedures in the ImageWriter II Technical Procedures. If the problem still occurs then it may be necessary to replace the paper deflector. After performing the adjustment verify that the paper deflector no longer moves when sliding the carriage back and forth.

LaserWriter Plus: Additional Error Codes

Revised: 8/2/88
Security: Everyone

LaserWriter Plus: Additional Error Codes

=====

This article last reviewed: 19 July 1988

BEFORE YOU START: Familiarize yourself with the LaserWriter Plus Technical Procedures, especially the section on the built-in diagnostics. Be sure to follow proper ESD procedures when replacing ROMs.

When using the built-in diagnostics of a LaserWriter Plus to test the ROMs on the I/O board sometimes an error code will occur that the instructions on error codes in the LaserWriter Technical Procedures do not help with. In all cases, only the last 2 digits of the error code are of concern.

If the error code was 024B 1E08, the H3 ROM and/or L3 ROM would be bad, or if the error code was 024B 1E80 the H7 ROM and/or L7 ROM would be bad, as indicated by the LaserWriter Plus Technical Procedures.

Now, suppose that the error code received is 024B 1E0A, since only the last 2 numbers have any meaning, we are only concerned with the "0A" at the end of the number. Decoding this error code becomes more difficult because error codes are added together if more than 1 ROM set is detected by the built-in diagnostics as bad. The addition is of 2 hexadecimal numbers so adding 08 and 02 in hexadecimal gives 0A and the corresponding error code 024B 1E0A. This indicates that there are possibly 4 bad ROMs instead of 2. In this example, the possible bad ROMs are either H3 or L3 and H1 or L1. This was determined by checking which of the error codes would add up to "0A" in hexadecimal.

Below is a list of other possible error codes that might occur. This list only gives those that would indicate 2 or more sets of bad ROMs. Be sure to refer to the LaserWriter Technical Procedures for more information on running and diagnosing the failures. If the error codes indicate several bad ROMs, the failure may be in the I/O board itself. In this event, exchange the I/O board.

High-Res RGB Monitor Cure for Jitters

Revised: 8/2/88
Security: Everyone

High-Res RGB Monitor Cure for Jitters

=====

This article last reviewed: 20 July 1988

Recently, dealers have reported a two phase problem with the High-Res RGB Monitor. To cure the jitter problem, they replace main logic board. Once the board is replaced, they find themselves with a strange convergence problem.

None of the adjustments listed in Tech Procedures (including V-Twist, H-Stat) cure the problem. Convergence can be as bad as 1/8" vertically. Adjusting the V-twist control only brings in a small section of the screen leaving the top and bottom borders way off. If the center section is adjusted correctly then the picture gradually get worse towards the top and bottom borders where distinct red, green (yellow), and blue shadowed images can be seen on the screen.

The part that made this different than a normal convergence problem was the fact that the shadowed images were all of different sizes. That is, green was larger than the red, and blue was smaller than the red).

The solution is amazingly simple: Adjust the V-Top and V-Bottom controls on the main logic board. This immediately brings the monitor into adjustment. No parts replacements were necessary.

Interestingly enough, this board was supposedly received DOA from the Campbell Support Center. It is possible that the apparent DOA condition was caused by a dealer technician bumping these potentiometers when installing the replacement board. It is also possible that these boards were not properly adjusted from the factory.

ImageWriter II: Keeps Printing Without Paper: Problem/Cure

Revised: 8/2/88
Security: Everyone

ImageWriter II: Keeps Printing Without Paper: Problem/Cure

=====

This article last reviewed: 20 July 1988

A common problem for older the ImageWriter II is that it continues to print after the paper has run out. The fix is easy: Replace the platen or use a solvent such as Fedron to clean the platen surface.

This works because the optical sensor assembly relies on the reflectiveness of white paper and the light absorbing characteristics of the black platen to determine when paper is installed in the printer. As the printer becomes older, the platen tends to take on a shiny (reflective) appearance from the build up of ink and paper deposits. Over time, this can reflect enough light to tell the the paper-out sensor that paper is in place when in fact there is no paper in the printer.

LaserWriter: Adjustments for Darkening Output

Revised: 8/2/88
Security: Everyone

LaserWriter: Adjustments for Darkening Output

=====

This article last reviewed: 20 July 1988

Dealers and customers report problems with the LaserWriter and LaserWriter Plus when printing dark areas. Dark areas of print are consistently lighter than on other Laserwriters printing the same document. Changing the toner cartridge has little effect. Further, the laser power adjustment shows that everything is within recommended specifications.

A Level 1 technician can solve the problem using Technical Procedures. First, remove the transfer corona assembly and look at the underside. You will notice that there are two clear plastic screws, one at each end of the assembly.

These screws raise or lower the corona wire 0.5 mm per revolution. Raising the wire increases the charge that attracts the toner to the paper from the drum thereby increasing the amount of toner pulled from the drum onto the toner.

Important: If problems earlier in the printing process restrict the amount of toner deposited on the photosensitive drum, then this adjustment will have no effect on the print quality. Therefore, be sure to troubleshoot the printer thoroughly and rule out other possible causes before performing this adjustment.

System Software 6.0: Known Problems

Revised: 8/2/88
Security: Everyone

System Software 6.0: Known Problems

=====

This article last reviewed: 20 July 1988

This article documents known bugs in System 6.0 software.

Sound Manager bugs

1. SoundAndMod purge bug:

"In low memory situations, SndAddModifier can purge the 'snth' resource before it is locked." This is the same problem as with SndPlay.

2. MIDI-In debug problem:

"When initializing a channel with the MIDI In synth. (7) the code drops into the debugger." A call to the debugger was inadvertently left in the code for 6.0.

3. MIDI amplitude scaling:

"Velocity values received from and sent to MIDI are scaled wrong." A scaling factor of two is missing in the code. The code runs fine, but can send some funny values for velocity.

4. MIDI timing to SCC on a Macintosh Plus:

"The timing to the SCC on the Mac Plus is wrong." The Macintosh Plus and SE need extra time after accessing the SCC. This is accomplished with extra instructions in the code. The macro we use in the MIDI driver code doesn't include enough of them (it has one but needs two).

5. SoundPlay purge bug:

"When memory is tight, SndPlay will purge the 'snd' resources as soon as it gets it."

6. Simple Beep is garbled

"On some Macintosh Plus and SE systems the simple beep is distorted."

Copybits bug in VideoWorks

"Copybits from a bitmap to a pixmap while in 8 bit mode." VideoWorks HyperCard driver is effected. The bug lies in QuickerGraf, and a 2 line fix was made.

Script Manager bug

1. "The Script Manager allocates too much space above the bufptr for some games."
2. "6.0 does not properly support IUDatePString and IUTimePString".
3. "KanjiTalk, which has not yet been built with 6.0, would not work with 6.0 because of a confusion in the definition of the area set aside for private and public verbs."

Palette Manager Bugs

1. "Provide support for devices that have no Color Look-Up Tables, that is, for boards like the E-Machine's board which only supports a fixed set of colors." This bug causes crashes in Adobe Illustrator and Color MORE when they de-reference NIL handles that would not be NIL in if a CLUT device was being used.
2. "The Palette Manager was calling Front Window at inappropriate times when the Window list should not be referenced." This bug causes the system to crash between applications that exercise the Palette Manager. Again, bad addresses are being de-referenced.
3. "When a window is hidden and DisposePalette is called, the palette in the hidden window was not disposed."
4. "The file system was being called during Disk Swap (SysErr)." This is a situation when things can be moved in memory. The file system will randomly crash when called."
5. "A colored menu bar was getting confused (and ugly)." This bug was caused by the fact that only the Apple in the menu bar was being redrawn with the Palette Manager. Now the whole menubar is redrawn. This is only a cosmetic bug, but it is a very safe and minimal change.
6. "When applications used the Palette Manager under both Single and MultiFinder, the Color Desktops would change to random colors. This looks extremely ugly." Again, this is only a cosmetic bug, but a fix was made to both the Palette Manager and MultiFinder to fix it.

MultiFinder Bugs

1. "If a volume is unmounted by an application other than the Finder (Disk First Aid, for example) the desktop database could be lost. This would cause the user to loose their Finder comments for that disk."
2. "The check for drivers in Background Apps is incorrect. This can cause slow response time on occasion, and conceivably cause crashes (though we have no specific cases reported)."

TextEdit Bug

"A de-referenced handle was maintained across a call that moved things in the heap. This could cause crashes."

MWS/MacAPPC Won't Work With IBM Application System

Revised: 5/10/89
Security: Everyone

MWS/MacAPPC Won't Work With IBM Application System

=====

This article last reviewed: 19 July 1988

MacAPPC and/or MacWorkStation will not currently work with IBM's Application System.

The IBM Application System is a 3270-based decision support tool, which runs under the MVS and VM operating systems, and is IBM's high-level decision support software product for business planning, statistical analysis, and project management.

The IBM Application System has extensions that allow direct access via DB2 and SQL databases and other IBM products, such as Query Management Facility (QMF) and Data Extract (DXT). However, it does NOT currently take advantage of intelligent desktop devices.

IBM says that "the direction of future development of the Application System product line is to provide support consistent with the need to use workstations that may have local intelligence" (or, simply, "it doesn't do it now, but it will someday.")

So, at present IBM's Application System supports neither LU6.2, IBM's flagship peer-to-peer protocol, or 3270 API implementations.

ImageWriter LQ: Bin Selection And Envelope Feeder Problems

Revised: 8/2/88
Security: Everyone

ImageWriter LQ: Bin Selection And Envelope Feeder Problems

=====

This article last reviewed: 21 July 1988

If you have installed additional feeder bins and envelope attachments to your ImageWriter LQ, you may experience one of both of the following problems:

Bin Selection: The application used with your ImageWriter LQ will not switch bins successfully. Even though you may want to print from first one bin, then another, the ImageWriter will only print the complete job from the first bin selected.

Envelope Feeder: With the envelope feeder fitted, the first envelope is fed through without being printed; then, several envelopes try to make their way around the platen at the same time.

The Solutions:

Bin Selection

This is an application problem -- not a print driver problem. If the application in use treats every page of a document as a separate print job, bin selection is negated.

For the bin selection to be effective, an application must know that a job consists of more than one page and that these pages are to be treated as extensions of the first page.

Envelope Feeder

For the envelope problem, try fanning and flexing the envelopes before inserting them into the feeder.

Another thing that might help is to load fewer envelopes in the feeder. Excessive tension caused by the weight of the envelopes or by having too many envelopes in the feeder may be creating sufficient friction between the

envelopes to cause the multifeed situation.

LaserWriter & LaserWriter Plus: Change Cleaning Felt Regularly

Revised: 8/2/88
Security: Everyone

LaserWriter & LaserWriter Plus: Change Cleaning Felt Regularly

=====

This article last reviewed: 21 July 1988

Some users have noted a problem with the Canon engine in both the LaserWriter and LaserWriter Plus that could lead to trouble without proper maintenance.

Under the green cover, which hides the fuser roller, are four orange rubber "fingers" that touch the roller. As toner builds up on these fingers, it crystallizes and becomes abrasive. This residue then scrapes off the teflon coating on the roller.

When the teflon coating wears through, toner no longer fuses to the paper at that position. (The finger on the far right as you face the roller seems to be affected the most.) The only fix at this point is to completely replace the fuser assembly, which is a very expensive solution.

You can prevent this from happening by ALWAYS replacing the cleaning felt (the green plastic strip that comes packed with the toner cartridge) every time the toner cartridge is replaced.

Macintosh: Avoiding Font ID Conflicts

=====

Article Created: 21 July 1988

Article Change History

03/29/93 - REVISED

- To encompass System 7.1.

TOPIC -----

Some of the fonts in my System are not showing up. After investigating, I found that some of the fonts have the same ID numbers. How do I prevent this?

DISCUSSION -----

If you find that two fonts with the same ID have been installed in the same system software, it is most likely the method of installation that is at fault.

System 6 and Before

When running System 6.0.x or earlier, always use the Font/DA Mover to copy fonts into the System file. This method will automatically resolve any font ID conflicts that exist. The Font/DA Mover is the only program that should be used to copy a font to or from any file under System 6.0.x or earlier. This ensures that all the necessary resources are copied with the font. The same applies for desk accessories.

System 7

This problem is rare in System 7. The proper way to install fonts in the System file is to drag them directly to the System Folder:

- With System 7.0.x, the fonts will be moved into the System file itself.
- With System 7.1 or later, when you drag fonts to the System Folder icon,

they will be moved into a Fonts folder within the System Folder.

HyperCard: Cannot Write Null Characters Without X-Command

Revised: 6/24/90
Security: Everyone

HyperCard: Cannot Write Null Characters Without X-Command

=====

This article last reviewed: 21 July 1988

There is, at present, no easy way for HyperCard to write a Null character -- hex 00 -- into a text file using "write <source> to file <file name>".

A Null character like hex 00 is often used as a formatting flag in text documents.

Here is a HyperCard script a user has written to demonstrate the problem:

```
on mouseUp
  open file "i/o test"
  write "+++" to file "i/o test" -- so we can see where the information starts
  write empty to file "i/o test" -- try to put the null constant into file
  write "*" to file "i/o test" -- a marker after the null char.
  repeat with x = 0 to 10
    write the numToChar of x to file "i/o test" -- try to generate it this way
  end repeat
  write "+++" & empty & "*" to file "i/o test" -- try to put a null in a string
  write "eof" to file "i/o test" -- write out an end of file marker for us
  beep 2
  close file "i/o test"
end mouseUp
```

Hypercard uses the C string format in which the Null is identified as the "end of string" marker. When HyperCard converts the variable in numToChar, the result of numToChar is placed into a container as a string, which in this case is a Null, interpreted as the "end of string", and thus ignored.

The only way HyperCard can currently place a Null character into a text file would be through an XCMD or XFCN.

AppleWorks: Superscript Codes For ImageWriter

Revised: 8/2/88
Security: Everyone

AppleWorks: Superscript Codes For ImageWriter

=====

This article last reviewed: 27 July 1988

Here are the codes to begin Superscript on an ImageWriter:

Superscript Begin: ESCAPE l1 ESCAPE r ESCAPE T20 CONTROL J
Superscript End: ESCAPE f CONTROL J ESCAPE T24 (66 lines per page)
Superscript End: ESCAPE f CONTROL J ESCAPE T18 (72 lines per page)

An ESCAPE c should not be used in the Superscript End code string. The ESCAPE c generates a carriage return which will, depending upon the setting for carriage return line feed, force all text following the Superscript end to be printed over the first part of the same line or on a new line.

Also, when giving the codes for Superscripting, the ESCAPE T20 may be adjusted to a greater or lesser value depending on the height of the desired Superscript. For 66 lines per page, an ESCAPE T value of 20 is almost a full character above the current text line, where as, an ESCAPE T value of 12 is about 1/2 character above the current text line.

LaserWriter IINTX: Available Fonts In HP LaserJet Emulation Mode

=====

This article last reviewed: 25 July 1988

LaserWriter IINTX's HP LaserJet Plus emulation provides access to the Roman, Bold, Italic, and Bold Italic faces for Courier, Times-Roman, and Helvetica fonts.

These are the only PostScript fonts accessible by the emulation. If other symbols or typefaces are desired, they must be purchased as downloadable fonts for the HP LaserJet Plus.

Font styles and typefaces on the LaserWriter IINTX in HP emulation are controlled with HP LaserJet Printer commands. If you need more direct information on font substitution, you can obtain an HP LaserJet manual. You can also purchase a utility like Hewlett-Packard's PCLPak Printer Software Utility (which does printer parameter modification). Such a utility will also download fonts to the HP LaserJet, but will not allow the definition of fonts.

Hewlett-Packard does provide many downloadable fonts for the PC. These fonts are provided in 3.5 and 5.25 inch MS-DOS disks, and cover most of the HP cartridge font units available for the HP LaserJet printers.

For more information, search under: Hewlett-Packard, Inc.

AppleShare PC: What All The Beeps Signify

Revised: 10/18/88
Security: Everyone

AppleShare PC: What All The Beeps Signify

=====

This article last reviewed: 25 July 1988

Users of AppleShare PC have asked about the alarm beeps that sound at various times during the printing process.

The beeps that a customer may hear most frequently are those found within the AppleShare DA program environment. These usually signify that the application doesn't understand something -- often an illegal key stroke.

The alarms that sound during a DOS application are a single beep and two trills:

- The single beep represents end of print job, and will occur regardless of whether the print job printed correctly or not.
- The first of the trills is an alert from AppleShare to check the DA for messages that have been received from the server or some AppleTalk application; this trill will repeat until the user executes the DA.
- Another type of trill will occur when the DA application is Hot Keyed, but cannot "pop up". This is because the application is not friendly to resident applications, and a DOS busy flag is set. The flag is then tested by the DA, and a trill is sounded when the flag is set. This tells the user that the DA has acknowledged the hot key, but could not "pop up" at that time.

The executing application keeps the stack and registers in such a way that a "pop up" application could erase necessary information.

Many PC applications trap the keyboard input, which input is also passed to other keyboard handlers as well, such as the Hot Key. If an application does not pass off the keyboard data, no alert will sound, and the DA will just not be available. The AppleShare application will still sound within these applications when an AppleTalk alert is received by the workstation.

AppleShare will also beep and display network timeout or errors when

connecting. These most often occur when connecting to a net with many zones.
Upgrading ROMS and software and reinstalling software seems to be the answer in most of these cases.

ImageWriter LQ: Sheet Feeder Must Be Removed To Use Pin Feeder

Revised: 8/2/88
Security: Everyone

ImageWriter LQ: Sheet Feeder Must Be Removed To Use Pin Feeder

=====

This article last reviewed: 25 July 1988

Some users have asked if pin feed paper (computer paper with holes on the edge) can be used in the Imagewriter LQ while the cut sheet feeder is installed.

In fact, you must REMOVE the cut sheet feeder from the ImageWriter LQ before using computer paper.

If you have the cut sheet feeder installed, a sensor in the printer will register this fact. There is another sensor which indicates which type of paper feed is selected.

When the cut sheet feeder is installed, and the paper feed lever is set to tractor feed, conflicting signals will then be sent to the CPU in the printer. One says "don't use the sheet feeder", the other says "use the sheet feeder". The result is an error light.

Also, since the paper guide must move the paper from the sheet feeder into the proper position for the platen rollers to pull it into the platen paper path. Thus, if you use the cut sheet feeder, the paper guide must be in place to allow the printer to place the paper correctly for printing.

Apple IIGS: Printing To A LaserWriter With ImageWriter Emulation

Revised: 3/23/89
Security: Everyone

Apple IIGS: Printing To A LaserWriter With ImageWriter Emulation

=====

This article last reviewed: 10 August 1988

Apple IIGS users who want to print to any type of LaserWriter using an application that does not support PostScript (such as AppleWorks) need to follow the following instructions:

Run Chooser II BEFORE using the LaserWriter from your application on an Apple IIGS. Chooser II works much like the Macintosh Chooser desk accessory, except that it is a stand-alone application. When the LaserWriter is selected, Chooser II will check the LaserWriter to verify the presence of the ImageWriter Emulator.

The ImageWriter Emulator (IWEM) is a PostScript file that is downloaded into the LaserWriter. If the IWEM is not present, Chooser II will download the file. If IWEM is present in the LaserWriter, Chooser II will acknowledge and not download.

The ImageWriter Emulator understands all of the standard features of the ImageWriters I and II, including boldface, underline, superscript and subscript in the default font, Proportional-1 font and Proportional-2 font.

The ImageWriter Emulator defaults to Courier at 12 characters-per-inch, unless you have specified Proportional-1 or Proportional-2 in the Open-Apple-0 printing options.

With ImageWriter Emulator version 1.1.2, Times Roman will be selected for Proportional-1 and Times Bold will be selected for Proportional-2. If you use the characters-per-inch option, this will cause Courier to be selected and printed at the CPI you specify.

Apollo To Macintosh II Connectivity

Revised: 8/2/88
Security: Everyone

Apollo To Macintosh II Connectivity

=====

This article last reviewed: 27 July 1988

Some users have asked about exchanging Interleaf documents between a Macintosh II running Interleaf, and an Apollo DN3000 workstation (also running Interleaf).

There are two methods of connecting the Macintosh II to the Apollo:

- A serial connection (either direct or via modem) using Kermit to move the file in either direction.
- Apollo has two network environments, Apollo's Domain and Ethernet. In the Domain environment, Macintosh and Apollo have no way to connect over the network. However, if the Apollo system has the Ethernet option installed, Macintosh and Apollo can move files via NCSA (National Center for Supercomputer Applications) Telnet & FTP.

For more information, search under: "Kermit File Transfer Protocol", and "National Center for Supercomputer Applications"

Apple Scanner: How Its Internal Circuitry Works

Revised: 5/24/89
Security: Everyone

Apple Scanner: How Its Internal Circuitry Works

=====

This article last reviewed: 12 August 1988

- Scanner circuitry

A scan is initiated when the microprocessor, inside the Apple Scanner, signals the carrier arm assembly electronics. At this point, the carrier arm, containing both the fluorescent lamp and CCD sensors, begins the scan. The scan proceeds line-by-line until the entire document is scanned. The reflected light from the scan is detected by the CCD sensors which are arranged in three rows of 2592 individual sensors. Each sensor in the first row holds one picture element (PEL), or pixel, of a scan line. The elements in rows 2 and 3 are used as data buffers prior to being sent to the image processing logic.

As the carrier arm assembly passes under the original document, the first row of CCD sensors capture the image reflection from the fluorescent light. The sensors produce analog signals that represent the original as tiny dots, or pixels, that make up a bit image. To manipulate and correct the various image distortions that can result from interference, the analog signal outputs from the CCD sensors are sent to the image-processing logic for conversion to digital signals.

The converted digital signals are sent either directly from the image-processing logic to the scanner main memory for transmission to the host computer; or, if the resolution is less than 300 dpi, the signals are sent through the line memory, PEL correction memory for transmission to the host. Data transfer from main memory to the host computer is done under control of the DMAC through the SCSI cable.

- Image-sensing circuitry

The components of the image-sensing logic include the CCD sensors and the analog circuitry which together are responsible for sensing, filtering, and amplifying the bit image of the scanned original. As the original is scanned, the CCD circuitry senses the image reflected by the fluorescent light. The

three CCD sensors are used to support one line of pixels. The second and third rows of sensors are primarily used to buffer the image data. The reflected light from each pixel charges the front-row of CCD sensors. The charged front row of sensors then shifts their contents to the second row of sensors which in turn shifts their contents to the third row of sensors. The third row of sensors are then serially shifts out, one element at a time, for clean-up and amplification. The signals from the amplifier, are then sent through a low pass filter and attenuator to the image processor where the signals are distortion corrected and converted from analog-to-digital.

- Flow of the CCD-sensing process

Also included in the image-sensing logic is the black-level reference voltage and auto background-adjustment circuitry. The black-level reference voltage determines the threshold value for the black level of the pixels; that is, will be represented as a black dot or white dot in the overall image. This part of the circuitry is driven by the seven signals (VBLO-6), from the microprocessor. The auto background-adjustment circuitry receives digitized signals from the image-processing logic to integrate the amplified CCD outputs as the background level. The integrated signals serve as the background level of the original and change dynamically during the scan.

- Image-processing logic

After the image has been scanned, the analog signals from the CCD elements are sent through the image-processing logic. The image-processing logic is responsible for processing the scanned image and contains the major portion of the scanner logic. The major components of the image processing logic are:

- DIPP (document-image pre-processor)
- Gate array 1
- Line memory and PEL correction memory
- Gate array 2

Most of the actual processing is done by the DIPP. The gate arrays, line memory, and PEL correction memory are support logic for the DIPP functions.

The DIPP is an image-signal processor which takes the analog image data from the CCD elements and corrects any distortion of the data, digitizes the corrected data, and transfers the digital data to main memory. These steps are accomplished with the support of the gate arrays.

In Line Art and Halftone composition scans, the DIPP passes the digitized signals to line memory for horizontal-resolution conversion for the selected resolution level.

The output from the DIPP differs depending upon the composition of the scan. When the scanner uses Line Art or Halftone composition, the output from the DIPP is 1 bit for every pixel. However, when the scanner uses Grayscale composition, the output is 4 bits per pixel. The additional bits enable the scanner software to create a more accurate representation of the individual

dots within the image. On the Macintosh II, the 4 bits drive the grayscale monitor or the color monitor.

The DIPP uses gate array 1 to support reduction options by controlling the line memory. When an image requires reduction, it is sent to the line memory for buffering prior to being sent to main memory. Gate array 1 also provides these additional functions:

- Address generation
- Memory control
- Bus interface
- Grayscale horizontal-resolution conversion
- CCD control

The PEL correction memory and line memory (2-Kbytes RAM) are used to buffer data from the DIPP before transfer to main memory.

Gate array 2 is used to support these functions of the DIPP:

- DMAC (two channel)
- Bus arbitration
- interrupt control
- Carrier arm-motor control
- Address latch
- Chip-select control

The microprocessor logic controls the functions of the gate arrays, DMAC, and carrier arm-motor control. The scanner uses an 8-bit NEC (7809) microprocessor. This processor runs at a 12-MHz clock rate and is supported by 256 bytes of RAM, an input/output port, a timer, and interrupt circuitry.

The clock-generation circuitry provides all the necessary timing pulses for the circuits in the scanner. The scanner has 2 separate clocks, a 12-MHz which is used by the microprocessor, and an 8-MHz clock used by gate array 2. Also, the 8-MHz clock is divided by 2 to provide a 4-MHz clocking for the DIPP, gate array 1, and the DMAC.

Main memory of the scanner contains two 16-Kbyte banks of RAM and 32-Kbytes of ROM. The ROM firmware is used to control the scanner, while the two banks of RAM are used to buffer the image data and provide the microprocessor with working space for parameter information.

The DMAC IC is used to improve the scanners performance by off-loading the burden of data transfer from the microprocessor. This process results in faster data transfer between the scanner and the host system.

Scanner Glossary: A Definition Of Terms And Graphic Formats

Revised: 5/24/89
Security: Everyone

Scanner Glossary: A Definition Of Terms And Graphic Formats

=====

This article last reviewed: 12 August 1988

Brightness:
refers to the overall whiteness of the scanned image.

Charge-Coupled Device (CCD):
is used to sense the reflected light as an image is scanned. It consists of three layers of elements, collecting each line of image data as an array. The first layer converts the reflected light into an analog signal while the second and third layers act as buffers.

Compositions:
is the methods of recording or interpreting scanned data. There are three common compositions: Line Art, Halftone, Gray-scale.

Contrast:
refers to the range between black and white; a low contrast would emphasize shades of grays where as high contrast would emphasize blacks and whites.

EPSF, Encapsulated PostScript File Format:
EPSF is the format used for importing PostScript files between many environments. This format was designed and implemented by Adobe. Basically an EPSF file follows the same standards as a PostScript file. Following is a brief summary of the exceptions: The EPSF file begins with a header of structuring comments which include: required comments (version, bounding box), general information comments (creator, title, date, end), font management comments (list of fonts in document, needed fonts) file inclusion comments (for including a separate file). A QuickDraw representation of the PostScript file may be saved in the resource fork in PICT format for screen display on a Macintosh. Or use MetaFile or TIFF for screen display in an MS-DOS environment. If a screen representation is not included, a gray box will be displayed matching the size defined by the bounding box in the header. These screen images can be manipulated within the application into which they have been imported. The application will be responsible for tracking the changes to the image and relaying this information in Postscript prior to the EPSF file.

Flatbed scanner:

is an imaging device where the document to be scanned remains stationary while the optical sensing assembly moves down the document one scan-line at a time much like a photocopier. This method allows for a more accurate scan and permits scanning of books or other thick materials.

Graymap:

is the relationship between the number of gray levels used in scanning and the densities detected in the original. The number of gray levels can be linear so that there is an equal number of light shades and dark shades or curved so that more variations would be detected within the darker tones.

Grayscale:

composition which records 4 to 8 bits of information for each dot, permitting 16 to 256 shades of gray. Grayscale requires large amounts of memory for data storage. Primarily used for scanning pictures which will be displayed on equipment that supports gray scales. Images created in gray scales are best stored either on large hard disks or CD-ROM.

Halftone Pattern/Dither:

is a matrix of threshold values that determine the patterns of black and white dots used to represent different shades of gray. The threshold levels contained in the matrix are applied to corresponding groups of scanned data. Primarily used for scanning pictures which will be displayed on equipment that does not support gray scales.

Halftone:

is the composition method of using combinations of black and white dots which form patterns to represent gray shades. Primarily used for scanning pictures which will be reprinted.

Image processing algorithms:

are used to manipulate the scanned data. An example would be inversing the scanned image.

Line Art:

is bi-level scanning which records only black and white data. This composition is used primarily for scanning text or line drawings containing no gray shades. Primarily used for scanning text.

Optical Character Recognition (OCR):

is software that enables a digitizing device or bit mapped image to be translate into editable text .

PICT:

Apple's QuickDraw Picture definition. The PICT file is a data fork file with a header, followed by a picture data structure. This data fork file contains a QuickDraw data structure within which a graphic application places drawing primitives, data structures that specify the geometry of basic graphical shapes, to represent an object or image graphic data. The pictures consist of opcodes followed by picture data. (Opcodes are predefined numbers which the QuickDraw function DrawPicture uses to determine what object to draw or what

mode to change.) PICT2 opcodes are 2 bytes in length. PICT2 opcodes support color QuickDraw. A picComment opcode provides a means for passing data and commands, that are not supported by QuickDraw, directly to an output device.

PTNG:

MacPaint Document Format. MacPaint documents use only the data fork. It contains a 512 byte header consisting of the version number and patterns, followed by the compressed data representing a single bit map of 576 x 720 pixels. The PackBits procedure in the Macintosh ROM is used to compress the data into 720 scanlines. This condenses a typical MacPaint document to 10K bytes that would occupy 52K of disk

Reflective Density:

is the measure of reflected light of each element. Black reflects less light than white, gray shades reflect varying measures between those of black and white.

Resolution:

is expressed in dots per inch. Most scanning devices available for the Macintosh are capable of reading images at resolutions of 75 dpi to 300 dpi. The selected scan resolution value should match the capability of the output device. For example, if the image will only be displayed on a Macintosh screen 75 dpi would be an acceptable resolution but if the output will be to a LaserWriter you would want to select 300 dpi as the resolution of the scanned image.

Scanning Digitizer:

consists of precision optical devices sensing light and dark areas of printed material by measuring reflected light.

Sheet-feed Scanner:

is an imaging device where the optical sensing assembly remains stationary as the document is mechanically fed through the device.

Threshold:

setting which determines the level or scanned density at which a gray shade is recorded as black or white.

TIFF:

Tag Image File Format. TIFF was designed through the combined efforts of Aldus and Microsoft for the interchange of digital image data independent of specific operating systems, file systems or processors. It has been designed for flexibility and ease of expanding to incorporate future advances in image processing (for example, color lookup tables). The TIFF file consists of a short header (specifying byte order, version number, offset to the Image File Directory), the Image File Directory (number of fields, field entries, next IFD offset), and the data. The field entry bytes contain the Tag, field type, length, offset to field value. A collection of fields describe the image.

Video Digitizer:

converts video signals into digital data. Because it is accepting video input you are able to digitize three dimensional and two dimensional objects.

Apple Scanner: Specifications (Discontinued)

Article Created: 12 August 1988
This article last reviewed: 9 September 1988

Technical:

Scanner type	Flatbed
Maximum document size	8.5-inch by 14.0-inch
Interface	SCSI
Dropout color	Green
Performance	20.4 seconds/11-inch, 300dpi scan, Line Art
Composition types	Line Art, Halftone, Grayscale
Grayscale	16 levels (4 bits)
Scaling	25% to 400%, depending upon output resolution
Output resolution	75 dpi to 300 dpi
Contrast levels	8
Brightness levels	16
Threshold values	16
Graymap settings	3
Halftone patterns	Spiral, Bayer, 2x2, Straght line, User-definable patterns, Adapive dithering

Physical:

Depth	21.8 in (545 mm)
Width	13.6 in (340 mm)
Height	4.4 in (110 mm)
Weight	20 lbs. (9.072 kg)

Power Requirements:

AC input (US and Canada)	120V AC+/-10%, 58 to 62Hz
AC input (Universal)	100/120/200/240V AC +/-10%, 48 to 62 Hz
Power consumption	Standby 35 Watts, Scanning 65 Watts

Environmental:

Noise (Maximum)	Standby <30 dbA, Scanning <55 dbA
Temperature	Operating Temperature +10 to +40 degrees C Storage (6 months) -40 to +47 degrees C Transit (72 hours) -40 to +65 degrees C
Humidity	Classified as Class 1 equipment

TOPIC -----

How To Get An AT&T Right to Copy (RTC) Licenses and Updates

DISCUSSION -----

Apple sells a subscription with an RTC for a given number of users and an update subscription for the same number. You receive only one software package, regardless of the number of copies you are licensed to create. You mount this copy on your server, so workstations can use it. Similarly, you receive one update software package and mount it for your users.

For example, if you buy an RTC for 10 users, you also need to buy a software update for 10 users. It doesn't matter if fewer than 10 users are active. You can take advantage of your remaining count when you add new users.

This structure is necessary, because Apple must track A/UX copies for AT&T's royalty reports.

UNIX: KIP and CAP Information (6/94)

=====
Article Created: 4 September 1988
Article Reviewed/Updated: 27 June 1994

TOPIC -----

This article discusses KIP and CAP software.

DISCUSSION -----

KIP is the IP-ETHER/APPLETALK gateway software used with the Kinetics KFPS. Developed by Bill Croft at SUMEX, Stanford University, KIP is public domain.

The Columbia AppleTalk Package (CAP) for UNIX was written by Bill Schilit and Charlie C. Kim of Columbia University. A library of routines enables a UNIX host to communicate using the AppleTalk Transaction Protocol (ATP), AppleTalk Session Protocol (ASP), Printer Access Protocol (PAP), Name Binding Protocol (NBP), and the AppleTalk Filing Protocol (AFP--client side). It, too, is public-domain software

The first major applications written using these libraries is the AppleTalk Filing Protocol UNIX File Server (AUFS), which is the server part of AFP. AUFS requires that AppleShare workstation software be installed on the client Macintosh. CAP includes applications that can be used to print to a LaserWriter, spool for a LaserWriter, and act as UNIX-based, AppleShare-compatible file server.

The CAP libraries currently require use of the UDP protocol from the DARPA TCP/IP suite of protocols and other features generally provided only in Unix systems based on 4.2 BSD Unix.

If you have Internet access, you can "ftp" the following KIP files from the <info-mac> directory on sumex-aim.stanford.edu machine. Use login name "anonymous" with FTP.

- at-kip.shar gateway and daemon source
- at-gw.srec latest gateway 'binary' in S-record hex format

- at-ddt.shar source for the network debugger.

The following information is from CAP distribution:

The CAP distribution is via anonymous FTP from cunixc.columbia.edu [128.59.32.130]. The directory is cap and the files in that directory are:

- INFO is an information file
- README contains release notes
- MODIFICATIONS is a list of modifications from distribution 4 to 5
- cap.tar.Z is the distribution in tar format "compress"ed using "compress"
- shar/cap50.1shar is the first half of cap dist - shell archive
- shar/cap50.2shar is the second half of cap dist - shell archive

A/UX: Imported AT&T 3B1 Code Won't Work Unless It's Re-Compiled

=====

Article Created: 24 August 1988

Article Change History

08/31/92 - REVIEWED

- For technical accuracy

TOPIC -----

This article discusses issues that have arisen when customers try to port code from an AT&T 3B1 to A/UX.

DISCUSSION -----

The customers have a large application already running under many UNIX platforms. The source to be ported is System V running on an AT&T 3B1. They have compiled very large object libraries which they would also like to port as object code rather than re-compile. The processor in the 3B1 is a 68010 and the customers were under the impression that object code for the 68010 would run under the 68020.

They tried compiling some of their own code and linking to an object library transferred from the 3B1, but the attempt failed. The attempt to transfer some standard C object code without non-standard library calls also failed. When they compiled the same C source code under A/UX, they noticed that the size of the object code was much larger under A/UX.

The following discusses the issues involved:

In theory, one could have 68010 object codes run under 68020, because 68020 machine instructions set is a super set of 68010. But with different architectures and/or operating systems (like the AT&T 3B1 and Macintosh II A/UX), you can't move object code to another CPU even though both are running System V (The current release A/UX is based on System V Release 2). Some

factors that might affect the upward compatibility between 3B1's Sys V and A/UX are:

- The data structure of systems calls might be different.
- The method of subroutine parameters parsing might be different.
- The stack addressing manipulation might be different.
- The internal registers usage might be different.
- The specific hard memory management unit (PMMU in Macintosh II A/UX might have a different approach to memory management.

The reason that the same C source code compiled under A/UX resulted in larger object code (assuming it is absolute executable code) than that which the 3B1 produced is that the 3B1 System V might run with shared library and A/UX does not have shared library. (A/UX 3.0 has shared libraries)

A/UX supports 4.2BSD-style signals and 4.2BSD-style networking system calls. It also supports the STREAMS feature which is normally available only with System V.3. Therefore, the library routines will not be identical with other System V software.

These are the reasons why directly porting 3B1 68010 object code to A/UX does not work without under A/UX without re-compiling.

Macintosh: How To Change Font Names (8/95)

Revised: 8/7/95
Security: Everyone

Macintosh: How To Change Font Names (8/95)

=====

Article Created: 23 August 1988
Article Reviewed/Updated: 7 August 1995

TOPIC -----

I've had problems changing the names of fonts. For example, the system shows both font names. This brings up questions concerning where font names are saved and what steps I should follow to change font names.

DISCUSSION -----

To rename a font properly, you must change the font's name in three places: the FOND, FONT, and sfnt resources. To change a font name, follow these steps:

WARNING:

The instructions in this article refer to using ResEdit to alter your system software. Apple Computer, Inc., is not liable for any damage done to your software through the use of ResEdit to alter the software. The User Assistance Center phone representatives (at 800-SOS-APPL) do not provide technical support for ResEdit. It is supported by APDA. For contact information on APDA, search the Tech Info Library under "APDA".

Step 1

Use ResEdit to open the System file or file that contains the font to be renamed.

Step 2

Find and open the FOND resource.

Step 3

Find the font name to be changed, and click it once.

Step 4

Go to the Resource menu, and select Get Info.

Step 5

Type the new font name in the Name field.

Step 6

Close the Get Info and FOND windows.

Step 7

Hold down the Option key and open the FONT resource.

Step 8

Click the font name to be changed.

Step 9

Go to the Resource menu and select Get Info.

Step 10

Type the new font name in the Name field.

Step 11

Close the Get Info and FONT windows.

Step 12

Quit ResEdit and ensure that the changes are saved when prompted.

NOTE: If you change the name of a font on one Macintosh and then move a document containing the font to another Macintosh that does not have the font name changed, you may have to reset the font manually.

FONT and NFNT resources are essentially the same, the main difference being that the FONT resource only allows 256 IDs while the NFNT resource allows 32768 font IDs. The sfnt resource is used for TrueType fonts and is documented in The TrueType Font Format Specification, APDA catalog number M0825LL/A. Also see the Macintosh Technical Note, "Font Family Numbers" and "Inside Macintosh."

A clean install of 7.0.1• gives no FONT resources. Apple recommends that developers use the NFNT resource, but the Font Manager uses either FONT or NFNT resources. A 7.0 system could still have FONT resources if the install was done over an existing system, or if older fonts are installed using the Font/DA Mover. Dragging a font suitcase onto the System Folder doesn't appear to create a FONT resource. There are no names in the NFNT resource, therefore those

resources do not have to be modified to change a font name.

Notes:

- Apple officially recommends that applications make all references to font families by name rather than ID number, however some applications may still refer to fonts by ID number. The difference between reference by name and ID may be a problem in Windows also.
- The sfnt resource contains a table with additional font name information that isn't in wide use currently, but may become used in the future. This could create problems when trying to rename fonts. This leads to this final disclaimer: Apple does not recommend that you rename fonts; you do so at your own risk.

Article Change History:

07 Aug 1995 - Reformatted, reviewed, corrected minor errors.

25 Nov 1992 - Included information about NFNT and sfnt resources.

MacWorkStation/MacAPPC Won't Work with an IBM Application

Revised: 5/10/89
Security: Everyone

MacWorkStation/MacAPPC Won't Work with an IBM Application System

=====

This article last reviewed: 20 July 1988

A customer is running IBM's Application System on an IBM 9370 and wants to redistribute some of the processing to the Macintosh. Can MacAPPC and/or MacWorkStation work with IBM's Application System?

Not yet.

Currently, the IBM Application System is a 3270-based, decision-support tool, running under the MVS and VM operating systems. It is IBM's high-level decision-support software product for business planning, statistical analysis, and project management. It has extensions that allow direct access via DB2 and SQL databases and other IBM products, like Query Management Facility (QMF) and Data Extract (DXT). It currently does not take advantage of intelligent desktop devices.

IBM says that, "The direction of future development of the Application System product line is to provide support consistent with the need to use workstations that may have local intelligence." This translates to, "It doesn't do it now, but it will someday."

As IBM's stated communications direction is SAA, many believe this product will eventually support LU6.2, IBM's flagship peer-to-peer protocol. Likewise, there is a strong possibility that it will support 3270 API implementations. Our information is that Application System supports neither of these implementations at the present time.

The Apple LU6.2 product has proven its interoperability with IBM LU6.2 via IBM's interoperability testing facility in Raleigh, N.C. Therefore, MacAPPC should work with this product when it supports LU6.2 protocol suites.

Presently, MacWorkStation, too, would be difficult to implement in this environment.

A/UX: How To Mount a Remote Toolbox Over NFS (9/94)

=====

Article Created: 20 July 1988
Article Reviewed/Updated: 1 September 1994

TOPIC -----

Some users have reported an NFS/ToolBox Problem.

In one instance, the systems have 40MB hard drives with only 20MB used by A/UX. To achieve this, users divided the total space required by A/UX between local disk storage and remotely mounted NFS disk storage across NFS on a VAX and a Sequent.

With this kind of mounting, however, Toolbox applications would no longer run. Most just crashed; however, "rez" produced the following error message while making %sample in "/usr/lib/mac/examples":

```
SysError(23)
pc = 0x1002653a (ROM = 0x10000000 -> 0x10040000)
Fatal error in Toolbox
```

DISCUSSION -----

Error 23 is an international utilities package load error documented as "package 6 not present". The A/UX System file, "/usr/lib/mac/System", may have been the problem. It was remote-mounted, and once it was copied back to the local machine, the problem disappeared.

You can get around the problem by keeping a local copy of the System file on each machine and using a symbolic link on the NFS-mounted file system to refer to the local copy.

A testing group reproduced the problem. After remote-mounting "/usr/lib/mac", they always got "Memory fault". However, removing "/usr/lib/mac" gave the same message with the text "core dumped" tagged on.

Note: Making "/dev/console" readable for all was not enough to run

`"/etc/toolboxdaemon"` as normal user.

The solution to this begins with the realization that `"/usr/lib/mac/System"` is a system-dependent file that must be found by the local `"/etc/toolboxdaemon."` To run Toolbox applications over the NFS:

1. Assume `"/usr/toolboxbin"` and `"/usr/lib/mac"` are not available in the local A/UX system but do exist in the remote NFS machine.
2. Launch `"/etc/toolboxdaemon"` from the local A/UX. (You don't need to be "root" to launch "toolboxdaemon". Any normal user can run "toolboxdaemon" if `"/dev/systty"`, `"/dev/console"`, and `"/dev/syscon"` are set mode to 0666.)
3. Mount a remote NFS machine; for example:

```
mount remote-machine-name:/ /mnt
```

4. Symbolically link a remote Toolbox Library to local machine; for example:

```
ln -s /mnt/usr/lib/mac /usr/lib/mac
```

5. Try to launch any Toolbox Application program; for example:

```
term
```

A/UX: biff Requires localhost in /etc/hosts File (8/94)

Revised: 8/24/94
Security: Everyone

A/UX: "biff" Requires "localhost" in "/etc/hosts" File (8/94)

=====

Article Created: 20 July 1988
Article Reviewed/Updated: 23 August 1994

TOPIC -----

Some users have tried to set up their systems for automatic notification of mail upon log in, but have failed. They report that although "biff y" in the ".profile" file works fine when in the Bourne shell, it fails in the Korn or C shell. Including "biff y" in both the ".login" and ".cshrc" files doesn't seem to help.

DISCUSSION -----

To solve this problem, first ensure that the "localhost" entry is present in the "/etc/hosts" file.

The "biff" notification is invoked by the sender's mailer (in this case, "/bin/mail"), which calls the "gethostbyname()" system call with "localhost" as its argument. This connects to the receiver's comsat server, which in turn alerts the receiver.

If your "/etc/hosts" file does not have the "localhost" entry, the "bin/mail" program will not try to call the receiver's comsat program.

Unfortunately, the "localhost" entry is not included in the distributed "/etc/hosts" file.

To make it possible for "/bin/mail" to connect to comsat, add the "localhost" name in the local loop back entry line in the "/etc/hosts" file:

```
127.0.0.1    localhost    loop lo loo
```

This doesn't work under any shell without the "localhost" name in the "/etc/hosts" file.

Apple IIGS: Printing To Networked LaserWriter (9/95)

=====

Article Created: 6 September 1988
Article Reviewed/Updated: 20 September 1995

TOPIC -----

I have an Apple IIGS on their network which has mostly Macintosh computers on it. Can you tell me what will happen if the Apple IIGS sends something to be printed, but the LaserWriter is already in use?

DISCUSSION -----

The Apple IIGS will respond in the same way as a Macintosh computer without background printing or spooling. The Apple IIGS will take its place in line and wait until the LaserWriter is available. Then the IIGS will print its documents.

• For accuracy.

Users who want to connect a Macintosh to Convergent Technologies equipment running their proprietary operating environment, CT*OS, take note:

Midwest Data Source makes a software package called Contact which will allow connection into BTOS (you can connect as a Burroghs MT-983, TD-730, or an ET-2000 terminal).

BTOS is an extension of CT*OS, and Contact supports the Burroghs B2X family running BTOS. The package supports also supports file transfer.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Macintosh: How To Disable Disk Eject

=====

Article Created: 4 August 1988
Article Last Reviewed: 18 June 1992
Article Last Updated:

TOPIC -----

How can I prevent someone from ejecting a floppy disk out of a Macintosh?

DISCUSSION -----

Some educational users have asked about disabling disk-ejecting procedures to prevent students from taking startup disks from their lab computers. Here are two methods:

1. Replace the Eject trap through an INIT so that the internal drive does not eject disks.

(NOTE: This is not completely effective, since the user only needs to restart the Macintosh while holding down the mouse button and the disk will eject. The student could also use a paper clip to eject the disk manually.)

2. Physically cover the drive opening. This would be the preferred method, since the student would not have access to the startup disk at all. When the Macintosh was restarted the disk would reinsert itself and the system would start up again.

Ergotron, Inc. makes a product, called "The Muzzle", that protects a Macintosh SE startup disk, as do other third-party companies.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

TOPIC -----

What are Apple's specifications for 256K and 1 MB SIMMs?

DISCUSSION -----

Here are the Apple specifications for 256 KB and 1 MB SIMMs:

Description: A Dynamic Random Access Memory Module organized by 8 bits in a 30 pin Single-in-Line-Package, comprised of:

- 256K X 1 bit Dynamic RAMs in Plastic Leaded Chip Carriers mounted on a PCB substrate.
- 1 MB X 1 bit Dynamic RAMs in SOJ packages mounted on a PCB substrate.

Pin #	Func.	Pin #	Func.	Pin #	Func.
1	Vcc	11	A4	21	/WE
2	/CAS	12	A5	22	Vss
3	D0	13	D3	23	D6
4	A0	14	A6	24	NC
5	A1	15	A7	25	D7
6	D1	16	D4	26	NC
7	A2	17	A8	27	/RAS
8	A3	18	NC*	28	NC
9	Vss	19	NC	29	NC
10	D2	20	D5	30	Vcc

Pin #18 is A9 on 1MB SIMM boards.

PIN NOMENCLATURE

Ax = Address input
/CAS = Column Address Strobe
Dx = Data Inputs/Data Outputs
NC = No Connection
/RAS = Row Address Strobe
Vcc = +5VDC
Vss = 0 VCD
/WE = Write Enable

Coarse pcb dimensions*:

1.27 mm thick
5.08 mm thick (incl. RAM)
16.8 mm tall
88.9 mm overall width
2.54 mm between pin centers

(*more specific dimensions available on request)

DYNAMIC PARAMETERS

ImageWriter LQ: How To Make The Ribbon Advance Correctly

Revised: 9/6/88
Security: Everyone

ImageWriter LQ: How To Make The Ribbon Advance Correctly

=====

This article last reviewed: 3 August 1988

ImageWriter LQ Ribbon Usage

The ImageWriter LQ is designed to do a ribbon shift per page on a multipage document, but every time you turn off the printer, the ribbon is reset back to band #1.

If your ImageWriter LQ doesn't step the ribbon down a track every page, it may be due to one of the following reasons:

- A tab on the left side of the black ribbon cassette (not present on the color ribbon) engages a switch that enables ribbon shift. It's possible that even if the tab is present and the ribbon is securely seated, the tab on the ribbon box might not press down the switch enough preventing the ribbon shift.

To work around this problem:

- Tape the switch down

OR

- Wrap tape around the cartridge tab, making it thicker so it will apply more pressure on the switch.

If you tape the switch down and the ribbon still doesn't shift, this indicates a non-functional sensor. The printer hardware requires service.

Macintosh System Size Varies With Amount of RAM Available

Revised: 9/6/88
Security: Everyone

Macintosh System Size Varies With Amount of RAM Available

=====

This article last reviewed: 4 August 1988

Some users have noticed that the amount of memory taken up by the Macintosh system seems to depend on the amount of RAM available.

For instance, in a Macintosh II with 1MB RAM, the system often occupies only 300-400K of memory, but in one user's Macintosh II with 8MB ram, the system took up 2.6 MB of memory!

The answer is to be found in the Start Manager, which on system startup assesses a number of variables, including:

- which microprocessor is present
- amount of RAM installed
- whether the RAM Cache is set and for what amount (although this has a greater impact on the application heap than on the system heap).

The Start Manager dynamically installs what it considers the optimum number of System resources, Fonts, Inits, DAs, drivers, to give the Macintosh the best performance. You do NOT have control over what system resources and code are installed at this point.

You can, however, control the amount of RAM consumed by extraneous Inits and RDevs, as well as the memory set aside for RAM Cache. Eliminate any extraneous CDevs containing Inits and RDevs, and choose a smaller RAM Cache setting -- or turn it off entirely.

As an example, eliminating a couple of CDevs such as Sound Master and ColorDesk could free up 650K of system heap space, memory that you may need for your applications.

HD Backup: Rejoining Backed-Up Files

=====

This article last reviewed: 2 August 1988

Some users have asked about recovering and rejoining data backed up on HD Backup:

- If one 3.5 disk is re-written, missing, or otherwise unrecoverable, HD Backup can not recover any of the other disks. Also, if a file is larger than 800K, it is split up and placed on separate floppies.

The best solution, of course, is to avoid the situation in the first place. WRITE PROTECT your backup diskettes, then use them only to restore files.

Once the problem has occurred, there are a few options for recovering the information:

- Insert the diskettes. From the Finder, copy files back to the hard disk.
- Rejoin split files using FEdit or some other utility

The second option might be a little challenging for some users:

DATA FORK

- If the data fork of the file is split over two disks, patch the files back together using Fedit's Multiple Sector Write, or a utility of your own.

RESOURCE FORK

- Rejoining a resource fork split over two diskettes is a little more complicated. The portion of the resource fork located on the first diskette should be normal. The portion on the second diskette contains a 512 byte header that should be disregarded. Again, rejoin the two halves with Fedit, or other utility.

AppleCD SC: Audio Specifications (Discontinued)

Revised: 9/13/93
Security: Everyone

AppleCD SC: Audio Specifications (Discontinued)

Article Created: 6 September 1988
This article last reviewed: 2 August 1988

Here are the specifications for the playing of compact audio discs on the AppleCD SC Drive. These are the minimum standards that the drives must meet before they are sold:

S/N ratio	>83 db
distortion	<0.01%
frequency range	20 - 20KHz
frequency response	100 Hz +/- 0.5 db
	20 KHz + 0.5 db
	- 3.0 db
channel separation	not specified

A sampling of AppleCD SC Drives were tested by Sony. Their test results show that the lot examined contained drives that exceeded our specifications:

S/N	90 db
distortion	.008%
crosstalk (channel seperation)	70 db

LaserWriter IINT: Setting up PostScript Connection To PC (4/95)

Revised: 4/21/95
Security: Everyone

LaserWriter IINT: Setting up PostScript Connection To PC (4/95)

=====

Article Created: 10 August 1988
Article Reviewed/Updated: 21 April 1995

TOPIC -----

This article describes how to use a LaserWriter IINT in the PostScript mode with a MS-DOS/Windows computer.

DISCUSSION -----

Step 1 - Connection

Connect a 25-pin Serial cable to the 25-pin serial port on the LaserWriter IINT. Connect the other end to a serial port on the PC.

NOTE:

Most serial ports for PCs use a male DB-25 connector. The LaserWriter IINT 25-pin serial port uses a female DB-25 connector. You need to use a null modem (transmit pin goes to receive pin) female-to-male DB-25 cable.

Step 2 - Switch Settings

While the LaserWriter IINT is off, set the printers DIP switch settings to:

- 1 UP
- 2 DOWN

These switch settings place the LaserWriter IINT in:

PostScript Batch Mode,
RS-232 9600 Baud,
RS-422 9600 Baud,
8 data bits , No parity check, 1 stop bit, with XON/XOFF handshake.

Step 3 - Power On

Turn on the LaserWriter IINTX and the PC. After a few seconds, the LaserWriter II will print a test page containing its current settings (as listed above).

Step 4 - PostScript Code

The PostScript code that follows is used to switch the LaserWriter II into 8 data bit PostScript batch mode.

Caution:

If you choose to use the PostScript code provided in this article, you assume all risks involved in making these changes. PostScript code, if not entered correctly, can place the LaserWriter into a condition requiring service.

NOTE:

The "%" characters and following comments are not necessary. You can remove them when typing in the program.

For DTR/DSR, from the DOS prompt type:

```
COPY CON POST.TXT
%=====
% Begin PostScript Code
%
serverdict begin 0 exitserver %This exits the printer server loop
statusdict begin           %Start modifying settings
25 9600 68 setsccbatch %set the 25 pin RS-232 9600 Baud port-8 data bits
end                         %This is the end of the mode switch routine
(control z)                %The keyboard control key and the z key together
%                           This ends text editing and saves the file.
%
% End PostScript Code
%=====
```

For XON/XOFF, from the DOS prompt type:

```
COPY CON POST.TXT
%=====
% Begin PostScript Code
%
serverdict begin 0 exitserver %This exits the printer server loop
statusdict begin           %Start modifying settings
25 9600 64 setsccbatch %set the 25 pin RS-232 9600 Baud port-8 data bits
end                         %This is the end of the mode switch routine
(control z)                %The keyboard control key and the z key together
%                           This ends text editing and saves the file.
%
% End PostScript Code
```

%=====

Step 5 - Batch File

A batch file needs to be created to set up the PCs communications port and to send the PostScript code to the printer. From the DOS prompt, type:

```
COPY CON POST.BAT
MODE COM1:96,N,8,1,P
MODE LPT1:=COM1
TYPE POST.TXT > LPT1
(control z)
```

Step 6 - Change to 8 data bit PostScript batch mode

Type POST from the DOS prompt to set the NT to 8 data bit PostScript batch mode. The printer will switch from the 7 data bit PostScript batch mode to 8 data bit PostScript batch mode.

Step 7 - PostScript Code for testing the mode change

The PostScript code that follows tests the mode change. From the DOS prompt, type:

```
COPY CON TEST.TXT
%=====
% Begin PostScript Code
%
/Helvetica findfont 14 scalefont setfont
30 500 moveto
(The Options number for the 25-pin port is ) show
statusdict begin 25 sccbatch 10 string cvs show
pop showpage
(control z)
%
% End PostScript Code
%=====
```

Step 8 - Test mode change

To test the mode change, type the following from the DOS prompt:

```
TYPE TEST.TXT > LPT1
```

After a few seconds, the LaserWriter II should print a page containing the following text:

'The Options number for the 25-pin port is xx'

('xx' equals the third number in the third line of the PostScript code created in step 4 (either 68 or 64).

Problem Solving:

=====

LaserWriter IINT does not print after test PostScript code is sent:

- Check cable connections and paper supply to the LaserWriter IINT. Turn off any spooler commands that may be implemented on the PC.
- Check the PostScript files (POST.TXT) and (TEST.TXT) along with the (POST.BAT) batch file for any typing errors. If none are apparent, try re-typing the code of both PostScript files from scratch. If you have the ability to copy and paste the PostScript directly from this article, you should do this.

If the LaserWriter IINT does not receive the PostScript code character for character, the mode change or test will not work. Once the code has been re-typed, send it to the LaserWriter II. If the LaserWriter II prints the page, then all is well. If the LaserWriter II does nothing, then start over from step #1.

LaserWriter IINT will not print from within an application:

- Check the applications print settings to ensure that it is sending output to LPT1 or COM1. The application must support PostScript, and must be set to output to a PostScript device.

NOTE:

The LaserWriter IINT does not support software switching between configurations, such as PostScript and Diablo, or LocalTalk and serial.

Article Change History:

- 21 Apr 1995 - Corrected Data bits and cable information.
- 22 Feb 1995 - Added PostScript caution and reformatted article.

LaserWriter IINT: Diablo 630 Emulation Mode (8/95)

Revised: 8/22/95
Security: Everyone

LaserWriter IINT: Diablo 630 Emulation Mode (8/95)

=====

Article Created: 21 November 1988
Article Reviewed/Updated: 21 August 1995

TOPIC -----

I need to print from my LaserWriter IINT in Diablo 630 emulation mode. How do I accomplish this?

DISCUSSION -----

Here is the method for serial connection from a PC to the LaserWriter IINT in Diablo 630 emulation mode:

1) Connection:

Connect an Apple 25 pin Serial cable (590-0037) to an Apple Modem Eliminator (590-0166). Connect one end to the 25 pin serial port on the LaserWriter IINT. Connect the other end to a serial port on the PC.

NOTE: Most serial ports for PCs use a male DB 25 connector. Since both ends of the Apple 25 pin serial cable are male, a female-to-female gender changer is required for connection to a PC serial port. An alternative is to use a straight pin-to-pin female-to-male DB 25 cable.

2) Switch Settings:

While the LaserWriter IINT is off, set the printers DIP switch settings to:

- 1 DOWN
- 2 UP

These switch settings place the LaserWriter IINT in:

Diablo 630 emulation,
RS-232 9600 Baud,
7 data bits, No parity check, 1 stop bit, with XON/XOFF handshake.

3) Power On:

Turn on the LaserWriter IINT and the PC. After a few seconds the LaserWriter IINT will print a test page containing its current settings (as listed above).

4) Set PC Communications port:

From the DOS prompt type:

```
MODE COM1:96,N,7,1,P
MODE LPT1:=COM1
```

NOTE: The LaserWriter IINT does not support 8 data bit Diablo emulation mode, meaning that ASCII characters 128-255 -- special graphic characters -- cannot be printed.

5) When printing from DOS, always follow the print command with a 'Control D'. A 'Control D' tells the LaserWriter IINT that the data transmission is completed, and printing can now begin. The best method is to create another text file with a 'Control D' inside. Enter the following from the DOS prompt:

```
COPY CON D.TXT
(Control D)
(Control Z) or (F6)
```

Now, make a batch file to send the end-of-page marker to the printer. From the DOS prompt enter:

```
COPY CON END.BAT
TYPE D.TXT > LPT1
(Control Z) or (F6)
```

After doing a TYPE or DIR to the printer, just type END, and the printer will print any remaining data in the buffer.

If your print job does not have a Control-D (end of page) character, you will have to wait for a job time-out for your print job or until another job is printed that is larger than a page.

NOTES:

The LaserWriter IINT does not support Diablo 630 mode over an AppleTalk network.

The LaserWriter IINT does not support software switching between configurations, for example, PostScript and Diablo or LocalTalk and serial.

There is also no available software for switching back to PostScript or any other emulation mode once leaving the PostScript mode. The correct method is to change the DIP switch settings and wait 30 seconds. If PostScript is desired, switch one should be set to DOWN. Wait 30 seconds and place switch back to the UP position.

Using Non-Apple SIMMs In Macintosh

Revised: 7/21/92
Security: Everyone

Using Non-Apple SIMMs In Macintosh

Article Created: 3 August 1988
Article Last Reviewed: 21 July 1992
Article Last Updated:

TOPIC -----

Many users have asked about the differences between Apple SIMMs and those in other vendors' products -- particularly physical size differences, speed differences, and parity checking.

DISCUSSION -----

Numerous third party vendors offer SIMMs that seem to work fine in the Macintosh. Although we don't specify the technical requirements of third-party SIMMs, many of those suppliers have either obtained Apple's specification or determined our system requirements, designing their chips accordingly.

Many of these vendors may be located by searching in Macintosh periodicals.

IBM is another computer manufacturer that is using SIMMs in their PS2s. Some differences are:

	Parity Checking	Basic Configuration	Speed
	<hr/>	<hr/>	<hr/>
IBM	yes	256Kb x 9 1Mb x 9	variable
Apple	no	256Kb x 8 1Mb x 8	120,150ns 120ns

A SIMM that provides for parity checking doesn't EXCLUDE that RAM from being used in a Macintosh. Such SIMMs could be used if all other timing

and pinouts were compatible, since the Macintosh will merely ignore that extra line.

Apple engineers have experimented with 2 IBM Model 30 256Kb x 9 SIMMs in a Macintosh Plus, and although the testing has not been extensive, these SIMMs have functioned using routine applications -- Excel, HyperCard, Microsoft Word, etc. -- and have passed a short and extended memory test.

However, just because these SIMMs appear to work doesn't mean that Apple can endorse the use of "IBM" SIMMs in our systems. IBM suppliers and PS2 third party vendors use differing RAM and designs to meet PS2's requirements, not ours.

Also, "IBM" SIMMs are available in a variety of speeds, including: 80, 100, 120 and 150ns. The 150ns chips should definitely NOT be used in a Macintosh II which requires at least 120ns SIMMs.

SIMM size:

- Apple currently uses surface mount technology (SMT) RAM, but there shouldn't be a problem using DIP through-hole chips. DIP chips tend to stand a little taller than SMT chips; but as long as they aren't so tall that they interfere with other SIMMs, they should work fine.

Another consideration is the height of the board itself: it must not be so tall as to interfere with expansion cards in a Macintosh SE (if any), or the chassis in a Macintosh Plus. However, there ought to be plenty of vertical room in a Macintosh II.

(NOTE: Apple LaserWriter SIMMs are physically and electronically incompatible with Macintosh SIMMs.)

Products That Enable Shared Serial Devices on AppleTalk

=====

This article last reviewed: 2 August 1988

If you need to share serially-attached products on an AppleTalk-based LAN -- such as Hewlett-Packard plotters, or HP LaserJets -- Mesa Graphics' Plot-It driver will drive a variety of plotters, including Hewlett-Packard models.

When used with Shiva's NetSerial product, Plot-It can drive a plotter over an AppleTalk network.

Both NetSerial AND Plot-It may be obtained through Mesa Graphics.

Sound Samplers: Descriptions of Some Third-Party Products

=====

This article last reviewed: 10 May 1989

MacLab System from WPI Instruments, Inc.

ADC and DAC in a box that connects to modem port of any Mac.
Sample rates to 40k/sec.
Comes with wave display and wave statistics software.

LabMaster II from Scientific Solutions

NuBus board for Mac II.
12-bit ADC, Two 12-bit DAC's, 24 lines of digital I/O, Five 16-bit counter/timers. Sample rates to 40k/sec. (100k/sec. with TM-100 option). Comes with "device drivers for multi-language application development."

MacAdios 411 from GW Instruments, Inc.

Add-on box that connects to modem port of Mac 128, 512, Plus or SE.
12-bit ADC and DAC, with 8 differential input channels and 4 output channels. Sample rates to 20,833/sec. 16 digital input lines, 16 digital output lines. Interface code in Microsoft BASIC and Aztec C, library of data acquisition/analysis routines.

MacAdios II from GW Instruments, Inc.

NuBus board for Mac II.
12-bit ADC and DAC, with 16 single-ended input channels.
(8 differential) and 2 output channels. Sample rates to 142k/sec.
8 digital input lines, 8 digital output lines. 3 15-bit counter/timers.
Up to 3 optional daughter boards can be added:
12-bit, 833k/sec ADC
12-bit, 142k/sec ADC
16-bit, 100k/sec DAC
16-bit, 16k/sec DAC
16-bit, 50k/sec ADC

Multiplexor card (additional 32 single-ended, or 16 diff. inputs)
Digital I/O (additional 16 digital inputs and 16 digital outputs)
Analog filter (programmable lowpass)
Prototype card

Interface routines callable from Aztec C, Consulair C, Microsoft BASIC, DCM FORTRAN, Lightspeed Pascal, Lightspeed C, library of data acquisition/analysis routines.

National Instruments NB-MIO-16 from National Instruments, Inc.

NuBus board for Mac II.

12-bit ADC with 16 single-ended input channels (8 differential).

2 12-bit DACs, 8 digital I/O lines, 3 16-bit counter/timers.

Sample rates to 40k/sec. Up to 111k/sec with optional convertors.

Can be set up for DMA if used with NB-DMA-8 controller card.

Strawberry Tree ACM2-12 and ACM2-16 from Strawberry Tree Computers

NuBus boards for Mac II.

Each has ADC and DAC. Number of analog and digital I/O channels depends on board option selected. Sample rates up to 500k/sec.

ACM2-12 is 12-bit, ASCM2-16 is 16-bit. On-board counter/timer.

Strawberry Tree ACSE-12 and ACSE-16 from Strawberry Tree Computers

Plug-in boards for Mac SE.

ADC with 8 differential input channels. 10k/sec. sampling rate.

ACSE-12 is 12-bit, ACSE-16 is 16-bit.

8 digital I/O lines. On-board counter/timer.

Comments

The GW Instruments MacAdios 411 box which has MacSpeech Lab software and MacSpeech Lab II for the Mac II. The MacSpeech Lab II package is useful for analyzing and editing digitized waveforms, especially speech or animal vocalizations. It has time-domain waveform displays, FFT, LPC, envelope and energy displays, and a grayscale spectrogram display.

The GW hardware and the boards from National Instruments can be used with the LabView software package from National. LabView is a Macintosh-like system for configuring data acquisition systems by connecting icons in a dataflow diagram. Strawberry Tree has a somewhat similar software package called "Analog Connection Workbench" that works with their hardware.

One bit of warning for anyone considering the purchase of a 16-bit sampling device that plugs into a computer slot. Just because the board has 16 bits of resolution does NOT mean that you can obtain 16-bits worth of wideband signal-to-noise ratio from it. That takes some very careful design work. Often, designers of these products are not primarily concerned with this kind of compact-disc-like noise level.

A/UX: Serial Buffer Size And Storage Issues

Article Created: 24 August 1988

Article Change History

08/31/92 - REVIEWED
• For technical accuracy.

TOPIC -----

This article discusses the input serial buffer, including questions concerning the default size of this buffer, whether it can be changed, and where the size of this buffer is stored. Answers involve the SCC (Serial Communication Controller) chip and the A/UX TTY device driver.

DISCUSSION -----

On the hardware side, the SCC chip has a three-character buffer. It is doubtful that the built-in buffer size can be changed.

The A/UX TTY device driver uses the "clist" style of character buffering. The "cblocks" in A/UX are only 26 bytes. This is a defined constant value in the kernel (#define CLSIZE 26 in /usr/include/sys/tty.h). To change it, you must re-compile the kernel.

In general, a hardware overrun error occurs, if the SCC buffer overflows because the input device driver doesn't read it often enough. A software overrun error occurs if an input device driver's buffer overflows because the application (like a communication program) doesn't issue read calls to the driver often enough, .

Macintosh To CDC Cyber Connectivity

=====

This article last reviewed: 25 August 1988

The only package currently known to Apple that provides connectivity from Macintoshes to CDC's (Control Data Corporation's) Cyber mainframe computers is called "CONNECT", and is available from CDC.

CONNECT provides terminal emulation and file transfers under protocol protection for the Macintosh. Terminal emulation supports both line mode and screen mode processing, and is augmented with features such as customized key definitions, use of color, national character set support, menus, configuration control, etc.

AppleTalk: A Discussion Of Problems Caused By Hello Broadcasts

Revised: 11/2/88
Security: Everyone

AppleTalk: A Discussion Of Problems Caused By "Hello" Broadcasts

=====

This article last reviewed: 29 August 1988

Customers with large networks comprising large numbers of computers (usually of diverse makes and kinds) have had to deal with two classes of AppleTalk problem.

The first problem has to do with the Routing Table Maintenance Protocol (RTMP) which causes AppleTalk devices to broadcast a "hello" message every 10 seconds, a message each device on the network must analyze. Some stated that Appletalk devices were the most talkative devices on the network.

The second problem is the limitation of 254 nodes on a single AppleTalk segment. Because there is no bridging provided by the standard EtherNet bridges AppleTalk sees all segments as one large network. Therefore, it does not take long to exceed this limit with Ethertalk and Fastpaths.

According to AppleTalk/EtherTalk engineering, if any workstations on a network have an AppleShare volume mounted, they will see increased traffic. When a workstation has an AppleShare volume mounted, it sends a request to the AppleShare server every 10 seconds asking for an update of the folder information for that volume. However, this is NOT a broadcast; it is a directed transaction to the AppleShare server that consists of one request from the workstation and one response from the server. This additional traffic should not cause a problem.

The only nodes that send broadcasts every 10 seconds are bridges and routers. They broadcast routing table information every 10 seconds, so that other routers can update their tables. Non-router nodes also listen to these broadcasts so they can keep track of a router address for next time they have to send a message across the internet.

Currently, EtherTalk (AppleTalk) network information packets also become Ethernet broadcasts. This means that non-AppleTalk nodes will get routing table and other broadcasts. A future release of EtherTalk will add a feature to send an EtherTalk broadcast that is NOT an Ethernet broadcast.

Lastly, AppleTalk/EtherTalk engineering is working on the AppleTalk's 254 nodes limit problem tentatively set for release in 1989.

CADAM Software on Macintosh

=====

This article last reviewed: 29 August 1988

For those of you running CADAM software on a Spectrographics workstation and storing files on an Amdahl Mainframe, here is some information to keep in mind:

While CADAM does output files in an IGES format when using the Mainframe version of the software, it does NOT output IGES format when running the mini or micro version of the software. To transfer a drawing into the Macintosh environment you need a utility like CadMover. CadMover converts IGES file format to other formats including those used by the Macintosh. Its capabilities include:

IGES -> MiniCad
IGES -> DXF
IGES -> MacDraw
IGES -> PICT
IGES -> MSC/pal

35mm Color Slide Makers: DICOMED DDC Format Conversion

Revised: 4/9/91
Security: Everyone

35mm Color Slide Makers: DICOMED DDC Format Conversion Utilities

=====

This article last reviewed: 29 August 1988

There have been requests for a product that takes presentation graphics (35mm color slides) prepared on a DICOMED system and converts them for use, editing, or display, on a color Macintosh II. DICOMED has two file formats. The "DDC" file format works with DICOMED's film recorder. The "DICOMEDia" file format works with other DICOMED equipment.

The 'DDC' file format is included in the film recorder's documentation. Currently there is no product that can translate DDC to/from Macintosh. However, with documentation available for both 'DDC' and Macintosh, a translator could be written.

The 'DICOMEDia' file format is propriety. An application exists that converts Macintosh images to the 'DICOMEDia' format. However, it does not convert 'DICOMEDia' to Macintosh. This program is available from Stradeware of Denver, Colorado.

For more information, search on "Stradeware".

System 6.0: Old Smart Alarms and Macromaker Incompatibility

=====

This article last reviewed: 2 August 1988

Some users may have had problems copying of files while running Macromaker under System v6.0.

One common problem occurs when the file name starting with a "." is reached. At this point, the Finder disappears and then restarts. The file with the "." is partially copied, and cannot be deleted until the system is rebooted.

This problem may be due to vestigial resources from Smart Alarms residing within the system. Many people used Smart Alarms until compatibility problems began to appear with System v5.0, and the remaining resources can cause even greater incompatibility difficulties with System v6.0.

One solution is for anyone who has previously used Smart Alarms to completely replace their system file.

However, Imagine Software has also made an inexpensive update for Smart Alarms which allows System v6.0 to function smoothly.

LaserWriters: How To Print Mathematical Symbols Under MS-DOS

Revised: 3/4/90
Security: Everyone

LaserWriters: How To Print Mathematical Symbols Under MS-DOS

=====

This article last reviewed: 13 March 1989

This article describes how to generate mathematical symbols on various models of the LaserWriter, from an MS-DOS application, like PC/Write.

LaserWriter IINTX

If you're using a LaserWriter IINTX in HP LaserJet mode, you can purchase from Hewlett-Packard the "Letter Gothic Base Set" (HP 33412A), 5.25-inch MS-DOS. The Math 7 and Math 8 fonts are included in this set, and these fonts can be downloaded into the LaserWriter for use in HP LaserJet mode. These are extended characters, meaning 8 bit mode must be in effect, both computer and printer. (The 8-bit mode lets the extended characters pass from the computer to the printer.)

Other LaserWriters

If you are using PostScript with a LaserWriter model other than the LaserWriter IINTX, your application should provide some method for dealing with different typefaces. Choose the Symbol font and type the key equivalent for the math symbols.

(NOTE: Printing the Macintosh screen while in Key Caps will provide a map to the Symbol key equivalents.)

AppleColor RGB Monitors: No Anti-Glare Facing For U.S. Models

Revised: 9/6/88
Security: Everyone

AppleColor RGB Monitors: No Anti-Glare Facing For U.S. Models

=====

This article last reviewed: 9 August 1988

The U.S. versions of the color monitor for the Macintosh II and the Hi-Res color monitor for the Apple IIGS do NOT have an anti-glare facing. UL, FCC, and CSA standards do not require such facing.

However, these monitors ARE anti-glare faced for some European countries. For example, Germany operates on the VDE standard which does specify an anti-glare facing.

Apple decided that the anti-glare facing detracted from the sharpness of the image on color monitors, and so specified that the anti-glare not be place on the color monitors except in those countries where required.

Apple does not know of any U.S. agencies currently working on an ergonomic specification of this type. Inside the US, the purchase of monitors with an anti-glare facing, or the addition of an anti-glare filter, is currently left to the discretion of the buyer.

Apple only performs reflectivity tests on those monitors which require certification of the anti-glare face to meet a specific country's requirements.

Current testing of the European monitors is done to meet the DIN 67530 standard:

- 15% - 75% reflectivity required @ 60% light incidence
- 20% - 50% reflectivity recommended @ 60% light incidence

3Com 3+: Some Incompatibilities With The Macintosh

Revised: 4/9/91
Security: Everyone

3Com 3+: Some Incompatibilities With The Macintosh

=====

This article last reviewed: 18 August 1988

Some users have asked about the AFP compatibility of 3Com's 3+ with the Macintosh family.

The 3+ network operating system for Macintoshes and MS-DOS compatible computers provides transparent file sharing between Macintosh and IBM PC-compatible computers. The 3+ software is only AFP-compatible in that you can use the software at the same time that you have an AppleShare volume mounted. The 3+ software was written before AFP specifications were made public, and does not implement any AFP calls. It has not been updated to use AFP.

3+Share software also looks quite different than AppleShare software. You cannot mount a 3+Share volume using the standard AppleShare chooser method. The interface for such tasks as network administration, setting passwords, and setting access privileges is not the same as the AppleShare interface, either.

The 3+ network operating system is an ALTERNATIVE to the AppleShare File Server and Print Server. It provides file service, print service, naming service, and internetwork routing service, and should be considered compatible with AppleShare only in that it doesn't actively interfere.

Why No Kana Operating System Exists For The Macintosh

Revised: 9/25/92
Security: Everyone

Why No Kana Operating System Exists For The Macintosh

=====

Article Created: 18 August 1988

Article Change History:

09/24/92 - REVIEWED

- For technical accuracy.

Some users have asked about a Kana operating system for the Macintosh. Not only is Apple not aware of any such OS, it is unlikely there would be one.

To better explain how this all works, let's look at how the Japanese written language has developed:

Japanese writing is a blend of four written character sets: Kanji, Hiragana, Katakana and Romaji. Characters from all four sets can occur in a single sentence. Hiragana and Katakana are two elements of what is known as Kana.

Kanji

Written communication in Japan began with the direct importation of the Chinese picture characters the Japanese call Kanji. Initially, each Kanji symbol was used in Japanese to represent a single word.

Kana (Hiragana & Katakana)

Eventually, the Japanese devised two separate phonetic syllabaries called Hiragana and Katakana, or simply Kana. Hiragana and Katakana are two different styles of writing the same sounds. Unlike the Kanji, each Kana character represents a syllable rather than a word or concept. Both are used in conjunction with Kanji to form the Japanese written system of today.

Romaji

..TIL03199-Why_No_Kana_Operating_System_Exists_For_The_Macintosh.pdf

Romaji are Roman alphabetic characters. These characters are rarely used except in dealing with foreigners and occasionally a company name.

Given these facts, a Kana OS would be a subset of KanjiTalk.

Macintosh: Serial Ports Do Not Provide Power For Peripherals

=====

Article Created: 1 July 1985
Article Last Reviewed: 30 June 1992
Article Last Updated: 30 June 1992

TOPIC -----

Is there any way to get power through the serial port to a peripheral?

DISCUSSION -----

Devices (such as modems) may NOT draw power from the Macintosh serial ports. On the Macintosh 128K, 512K and 512K enhanced (which use DB-9 connectors for the modem and printer ports), Pin 6, the +12V pin, is strictly a power-on indicator and may not be used as a power source of any kind.

Macintosh Plus and later computers (which switched to Mini DIN-8 connectors for the serial ports) lack the +5 and +12 Volt signals from the earlier models.

Despite warnings from Apple that the +5 and +12 Volt signals found on the DB-9 serial ports on the 128K and 512K Macintoshes could be removed in the future, some manufacturers designed peripherals that relied on one or both of those signals. These peripherals (e.g. Thunderscan) may not work properly on a Macintosh Plus or later Macintosh due to the removal of the above-mentioned signals. If this is the case, contact the manufacturer of the peripheral for a suggested solution. Some manufacturers offer external power supplies to take the place of the absent signals.

This change also means that a Macintosh application may have to control a peripheral's DTR line.

The serial ports from the Macintosh Plus and later models do not provide power for any peripheral devices. The DTR line (Pin 1) is intended to provide an output handshake signal only, NOT to power external devices.

Any devices connected to the serial ports of the Macintosh Plus or newer models must get their power from an external source, separate from the Macintosh system. Apple does not support devices that receive their power from serial ports.

The solution is to use a separate power source to supply the voltage needed for these modems or peripherals.

AI: Some Working Definitions Of The Terminology (Part 2 of 2)

=====

Article Created: 19 August 1988
Article Last Reviewed: 9 June 1992
Article Last Updated:

This article continued from "Working Definitions Of Some "AI" Terminology (Part 1 of 2)"

Expert Systems:

Computer systems that address subjects previously requiring a human expert on hand. An excellent example of this is AppleCat diagnostics from Apple. This software can be used to isolate a Macintosh hardware problem that previously required a service person (expert).

Flavors:

The Object Orientated Programming implementation used by the Explorer.

Garbage Collection:

LISP programs inherently involve frequent memory allocation and deallocation. Garbage collection is the process of reclaiming memory that was allocated, but is no longer required by the application. While LISP machines address garbage collection through hardware, any conventional machine must duplicate this effort in software, typically forcing frequent delays while waiting for the machine to return to the user (think of printing with and without a spooler). This is one of the reasons for the claim that LISP is a slow language or could never be used for real-time processing.

LISP Language vs. LISP environment vs. LISP machine:

The LISP language is the implementation of LISP, the syntax of the language.

Most of the industry recognizes that Common LISP is becoming the standard language for LISP. When we talk of a LISP environment, we are referring to the programming features offered to assist one in programming in LISP, such as the LISP listener (interpreter), debugger, inspector, object-oriented programming implementation, compiler, tag implementation, and garbage collection utilities to name a few. These are available (in a varying degree) for whatever LISP you are using. When we mention a LISP machine, we are referring to a processor/computer built specifically for running the LISP language, with hardware features optimized to run LISP.

Knowledge Engineering:

Using AI programming techniques (methodologies) -- such as knowledge representation, search, or reasoning strategies -- to solve applications requiring symbolic processing.

Knowledge Engineer :

This title gets a lot of attention these days, and often a considerably higher salary for the software developer/ programmer/ analyst familiar with AI programming techniques, languages and shells and their proper implementation.

LISP Machine:

A computer specifically designed to run the LISP language. Includes hardware support for critical "LISP" functions, such as garbage collection and data type processing.

Object Orientated Programming:

A method of programming with abstraction that allows a more natural representation of real world items (or objects). An object can be defined as a "class" that can have associated or inherited procedures, arguments, or component-objects.

An example of this is to define a new "class" of object called "COMPUTER". Each COMPUTER can be defined to have associated with it such items as a keyboard, monitor and CPU. New classes can then be defined based on this class -- a "MACINTOSH" can be a type of "COMPUTER", and as such we can assume that it has a keyboard and monitor.

When we create this new class MACINTOSH, we can also define a default CPU type of 68000. We could go on and define a procedure for the MACINTOSH called HOW-TO-RUN-APPLICATION which has a value of CLICK-ICON, (whereas the procedure for the original COMPUTER class may have an associated HOW-TO-RUN-APPLICATION value of ENTER-ARCHAIC-COMMAND). The idea is that with Object Orientated Programming, we are able to define objects in a way that more closely associates how we naturally think of the objects. Also, once we know an object

is defined, and what values it has, we don't have to worry about HOW it was defined -- as long as it works. This leads to a "Black Box" approach, where we do not concern ourselves with what is in the Black Box as long as we know it is available and works.

Rapid Prototyping:

The process of using a short "develop-test-modify" cycle, with frequent feedback, as a way to help define the final system solution. The idea is to work on the conceptual level to define a proper solution and worry about the final implementation details later, as opposed to a programmer spending significant time in development, only to arrive at a working solution that does not address the original problem correctly.

Tagged Architecture:

Hardware support for implementing Data Type Processing on LISP Machines. This allows processing "tags" in parallel with other instructions. Any conventional hardware running LISP must duplicate this effort in software.

AI: Some Working Definitions Of The Terminology (Part 1 of 2)

=====

Article Created: 19 August 1988
Article Last Reviewed: 9 June 1992
Article Last Updated:

As with any other computer field, "AI" (Artificial Intelligence) has a distinguishing set of buzzwords. Following are a few working definitions that either are used in this paper, or that one can expect to hear when talking with a typical "AI" professionals.

Artificial Intelligence, or AI:

Trying to define AI is similar to trying to define exactly what HyperCard is to someone who has never seen it (or worse, never worked with a Macintosh). The field of AI includes many areas, such as speech, vision, robotics, natural language interfaces, neural networks, machine learning, automated programming, intelligent agents and expert systems. Typically, when someone thinks of AI, they are associating a computer/robot with a more specifically human activity (thinking, seeing, hearing, understanding, moving).

Common LISP:

With the various versions of LISP available, Common LISP is recognized as the emerging industry standard for LISP today. This should help lead to a portability and consistency among architectures, allowing a complex problem to be developed with a LISP machine, while being delivered on a less expensive, possibly non-LISP architecture.

Conventional vs. Symbolic Processing:

Conventional software has typically been used for problems that are more algorithmic or numeric in nature and well understood, with the computer use being to perform very rapid calculations or to process very large amounts of

data in an orderly fashion.

Symbolic processing deals with information that is more conceptual ("symbolic") in nature, such as: "Given a certain CAD/CAM/CAE design criteria, what is the ideal design (lowest cost, most accurate, simplest to manufacture, most reliable)." While people will typically argue that you can do anything with any language (given enough memory, disk space, programmer time...), the main advantage of symbolic processing is to free the programmer/developer from dealing with the lower levels of implementation, allowing him to focus on a higher, conceptual level of abstraction to address his real problem at hand.

Another way to think of symbolic processing is the concept of symbols. Typically a symbol represents more than just physical definition. If someone asks for a "pen", they are probably not as interested in the physical features (gold cross, BIC, apple logo or size = 5.75 inches) but rather are asking for something that will write in ink.

Data Type Processing:

LISP programs typically use a "tag" implementation that allows data types to be checked at run-time, as opposed to mandating that data types be declared in advance. This gives applications more flexibility to deal with complex and changing situations over the development life cycle.

Development vs. Delivery machines:

This distinction indicates the difference between the computer system on which an application is developed , and the computer on which the final application is delivered to the end user.

An example: a company might use a LISP machine and AI software package (which may total well over \$100,000 for initial hardware/software costs) to develop a solution, but deliver it on a microExplorer or Mac II for a much lower cost per end-user. The idea is to have the ideal development environment to save development cost and increase programmer productivity, while also being able to deliver the solution in a relatively inexpensive environment.

Domain Expert:

One typically recognized as an expert in a field (domain).

This article is continued in "AI: Some Working Definitions Of The Terminology (Part 2 of 2)".

Apple IIGS: The Differences Between Spanish And USA Characters

=====

This article last reviewed: 24 August 1988

The differences between the Apple IIGS's USA character set and its Spanish character set are listed below. The USA characters are found on the key caps. The Spanish character is displayed when Spanish is selected from the Control Panel. All other keys generate the characters displayed on the key caps.

USA	Spanish
---	-----
[upside down exclamation mark
]	upside down question mark
\	lower-case "n" with tilde above
	upper-case "N" with tilde above
{	degree symbol
}	lower-case "c" with cedilla
#	British pound (currency) symbol
@	section symbol

The standard "?" was generated using the shifted backslash in both USA and Spanish character sets. We were unable to locate the right accent mark in either character set.

(Unfortunately, the current version of AppleLink is unable to reproduce these special characters graphically, which is why we can't just show you the characters in this article.)

LaserWriter IINTX/IIf/IIg: Third-Party Hard Drive Compatibility

=====

Article Created: 24 August 1988
Article Last Reviewed: 8 April 1992
Article Last Updated: 8 April 1992

TOPIC -----

What third-party SCSI hard drives are compatible with the LaserWriter IINTX and LaserWriter IIf/IIg?

DISCUSSION -----

Apple doesn't maintain a formal list of compatible third-party hard drives. The following information explains the conditions for compatibility.

To use a third-party drive with the LaserWriter IINTX, two conditions must be met:

- It must report SCSI termination power to the printer.
- It must report the volume size to the printer.

To use a third-party drive with the LaserWriter IIf/IIg, an additional condition must be met:

- It must report the SCSI unit attention command to the printer.

If these conditions are not met, the formatting fails and the hard drive will not work with the printer.

Note

Even when all conditions are met, some drives still may not be compatible with the printer. If you experience this problem, contact the hard drive manufacturer for compatibility information and possible workarounds.

HyperCard: HyperMIDI And MIDI XCMD

=====

This article last reviewed: 10 February 1989

Here are two XCMD sets for interfacing HyperCard to MIDI devices:

HyperMIDI 1.1a is a set of XCMDs for sending and receiving MIDI data from within HyperCard. It comes with several cards demonstrating different methods of managing MIDI data. One of the features of the XCMDs is the ability to place graphic sliders on cards. These sliders can be assigned to control any MIDI parameter.

HyperMIDI is available on many electronic bulletin boards and commercial software distributors.

A second set of XCMDs for HyperCard and MIDI is MIDI XCMD. This stack is not as fully featured as HyperMIDI, but will allow the recording and playback of your MIDI performance.

MIDI XCMD is available on many electronic bulletin boards and commercial software distributors.

AppleShare PC: Why It Can't Delete Extension Mapping Icons

Revised: 10/18/88
Security: Everyone

AppleShare PC: Why It Can't Delete Extension Mapping Icons

=====

This article last reviewed: 30 August 1988

AppleShare PC users have asked how to eliminate an unwanted Macintosh icon mapping -- for instance, an inadvertently-created "extra" DOS filename extension.

Actually, the number of extension mapping icons are static: they cannot be deleted. However, a file extension can be changed back to default, or to some other extension.

GENERAL INFORMATION:

AppleShare PC automatically sets a Macintosh file icon type for files created on file server volumes. These type assignments are based on the three-character DOS filename extension. DA also uses the file type and file extension information to recognize DOS text files and Macintosh file text files for potential conversion while copying.

Change Extension Mapping lets you select an icon type for a given file extension. This icon type will be assigned to all appropriate new files created on server volumes; existing files are not affected. For example, you can set all files that you created with the extension WXT to be file type Binary; whenever you create a file whose extension is WXT on the file server, it will automatically be assigned the Binary icon.

To see a list of already-mapped extensions (other than Binary), at the DOS prompt enter the command: ANET MAP

You type the extension of interest at the Extension prompt. (You don't type the initial period, and wildcards aren't allowed.) You press the Enter or Tab key to move the Type pane; then press the number of the type you want to associate with the extension you type. (You can also use the Up and Down Arrows keys to move through the list in Type pane.)

Icons for files on the server at the time you set the mapping remain unchanged.

You can change the icon type of an existing individual DOS file. Pressing F2 brings up an information window on the icon highlighted. You can change the file's type to any listed by pressing the number of the type you want to use. (Use the Up or Down Arrow key to scroll through all options.)

AppleFax Modem: Wrong-Tone Problem May Be Misplugged Cable

=====

This article last reviewed: 30 August 1988

Here is a problem some users have experienced:

When the AppleFax Modem software is loaded, and another fax machine tries to dial in, the software on the AppleFax Modem station asks the user if it should answer the phone.

When the end-user selects "Answer Phone", the person at the AppleFax Modem hears the series of tones used to establish the connection between the 2 fax machines. However, the originator of the phone call still hears that the phone is dialing, and that the destination AppleFax Modem HAS NOT answered the phone call.

This is probably because the phone cable between the AppleFax Modem and the wall is plugged into the wrong RJ-11 jack (the one with the telephone icon below it) on the back of the AppleFax Modem.

The phone cable between the AppleFax Modem and the wall should be plugged into the RJ-11 jack with the RJ-11 icon below it.

LaserWriter Plus: Understanding How Font Downloading Is Handled

Revised: 9/6/88
Security: Everyone

LaserWriter Plus: Understanding How Font Downloading Is Handled

=====

This article last reviewed: 31 August 1988

Users who have created a bitmapped font (with Fontographer) and installed it in their system, then designed a spline (printer) font and written it in PostScript have asked:

What can be done so the Macintosh application will automatically download the font to LaserWriter Plus when using the screen font.

When both the bitmapped (screen) font and the spline (printer) font have been designed in Fontographer, there are two methods of downloading available:

1. Many Macintosh applications will automatically download fonts to the printer as they are needed. Whenever such a program needs a font that is not already in the printer, it searches the Macintosh disk drives for a file containing that font and downloads it. The font files must be in the current folder, the root directory, or the system folder of the startup disk. They may also be on an on-line server, if one is available. When automatically downloaded, a font is deleted at the finish of the document for which it was chosen (or, for PageMaker, at the finish of the text block.)
2. You can also download fonts to the printer manually, using the font downloading program supplied with Fontographer. When manually downloaded, a font remains in the printer, ready to be used, until you turn the printer off.

CAUTION: For most applications, four to six fonts can be downloaded to the printer before it runs out of memory. The actual number depends on the particular printer, applications and fonts you are using. (The LaserWriter IINTX with expanded memory provides more than described) If the fonts sent to the printer, both manually and automatically, exceed the printer's capacity, the printer will restart itself, ejecting a startup page and erasing all the downloaded fonts.

If some method other than Fontographer is used to generate the PostScript spline (printer) font, it is likely that the screen font and the printer font will not properly bond to one another.

Fontographer provides the proper bonding that is required for screen and printer fonts. If it is possible to open the PostScript printer file with Fontographer, Fontographer should then be able to generate the properly bonded screen and printer font files.

Tandy TRS-80 to Macintosh Connectivity

=====

This article last reviewed: 8 September 1988

To transfer text files from a Tandy TRS-80 Model 4 to a Macintosh, you can attach the Macintosh via RS-232 cable and make the TRS-80 think the Macintosh is a printer. This is a simple inexpensive solution, necessary because the TRS-80 uses TRSDOS, a disk operating system that is not compatible with other systems' 5 1/4 inch floppy diskette formats. Here's how to do it:

- 1) From an appropriate application, save the files you want to transfer as text only.
- 2) Convert these files from TRS DOS 1.3 to TRS DOS 6.0, if necessary. This is required because the commands in steps 3 and 4 are not supported in 1.3. This is done using the TRSDOS 6.0 command CONV, which can be applied to a whole disk (for example, CONV :1 :2) or to a given file (for example, CONV filename:1 :2).
- 3) To set *CL (the RS-232 communication line device) to the appropriate driver, issue the command SET *CL TO COM/DVR
- 4) To direct print output to the RS-232 port instead of the parallel port (the default), issue the command ROUTE *PR TO *CL
- 5) For each file, issue the command LIST <filename> (PRT). This will "print" the file to the serial port.

Microsoft Works is a good program to have on the receiving end of this process, because it doesn't add the unwanted carriage returns that plague other communications program. Use the "Capture Text" choice under the Communications menu to specify where to save incoming data.

A/UX 3.0.x: Compliance With POSIX Standard (9/94)

Revised: 9/19/94
Security: Everyone

A/UX 3.0.x: Compliance With POSIX Standard (9/94)

=====

Article Created: 12 September 1988
Article Reviewed/Updated: 19 September 1994

TOPIC -----

This article describes A/UX compliance with the POSIX Standard.

DISCUSSION -----

On August 1, 1988 at Uniforum, Apple announced a release of A/UX that meets current draft 12 compliance. As with other vendors, we are waiting for a formal Portable Operating System Interface for Computer Environments (POSIX) standard to be validated.

A/UX version 3.0.x is POSIX compliant as follows:

- POSIX 1003.1b - yes
- POSIX 1003.12 - no
- POSIX 1003.2 - no

Below is a brief description of POSIX 1003.1b, POSIX 1003.12, and POSIX 1003.2.

POSIX 1003.1b: Is part of POSIX 1003.1, and POSIX 1003.1 specifies interfaces to basic system services such as processes, the file system, I/O, devices, and related identifiers and environment variables. POSIX 1003.1b is for things that did not get into POSIX 1003.1a in time for various deadlines.

POSIX 1003.12: Addresses "Protocol Independent Interface" on top of the transport layer, which include both BSD sockets and AT&T TLI (or XTI which is X/Open's version of AT&T TLI), plus DNI and SNI. DNI stands for Detailed Network Interface, it is a general interface to the transport layer, and can be used for most network programming. SNI stands for Simple Network Interface, designed for applications that do not need the flexibility of DNI. Applications can talk to either DNI or SNI or both, both DNI and SNI can talk to either sockets and/or TLI(XTI).

POSIX 1003.2: Specifies programming interface to the shell and related utilities, it has two parts. The first part (largest) describes the facilities required for the portability of shell scripts. The second part is called "User Portability Extension" (UPE), which includes interactive commands required for user portability, such as: vi.

Fonts: How Screen Fonts And PostScript Fonts Are Associated

=====

Article Created: 8 September 1988

Article Change History

09/10/92 - REVIEWED
• For technical accuracy.
02/02/91 - UPDATED

TOPIC -----

If I'm not using Fontographer, and the bitmapped font is defined (using ResEdit, for example), and the spline font has been defined in raw PostScript, how are the two fonts "bonded" together?

That is, how are the two fonts connected so that the Macintosh knows when the bitmapped font is referenced it should look for and download the "bonded" PostScript font?

DISCUSSION -----

The necessary resources for font reproduction on a LaserWriter, when using a printer font, are:

- The screen FONT
- The printer FONT
- FOND

The screen FONT is used to select the desired font from within an application. The printer FONT is a defined font, either a bit-map or B-spline for a PostScript printer.

The FOND resource is needed to list the associated FONTS for the Font and Printing Managers to select an appropriate font. Because the user does not

have a FOND to list the association of the spline font with the screen font, the Print Manager cannot select the printer font to be downloaded.

When you give the LaserWriter driver a screen font to print, the driver queries LaserWriter for a list of available fonts. If a downloadable font is not available but is listed in the screen font's FOND resource, that font is downloaded and used for printing.

The method of designating the downloadable font is to provide the downloadable font within the FOND resource, a font class, and a font name.

A font, previously downloaded, can be "uncoordinated." That is, it does not need to be referenced in the FOND listing, because when querying the LaserWriter, the LaserWriter driver selects the name of the pre-downloaded font. In the case of a font that is temporarily downloaded, the font must be "coordinated" with the screen font in the FOND.

The style-mapping table of the FOND resource contains the font class as the first two bytes. The font class designators of the LaserWriter driver v3.0 contain 16 (0 to 15) values (10 through 15 are reserved).

Font class designators describe the font and allow or disallow encoding functions, like condensing or outlining.

The style-mapping table contains indexes of all downloadable font names for the font's available styles. If the font name is found in the table, the Font Manager searches for the font in root directories of all available volumes. The name is determined by the first five letters of the font name in the style-mapping table and the first three letters of the font style. The first letter of the base name and the first letter of the style suffix are capitalized.

The resource type of the downloadable font must be an unbundled "LWFN" whose creator is "LWRT". It is suggested that the font information be kept in several "POST"-type resources, rather than one with IDs beginning with 501 decimal. This avoids memory conflict during loading of the font resource. Each resource must begin with a two-byte data field containing the data type in the first byte and binary zero in the second. The balance of the resource is the data to be downloaded. The data type consists of values 0 to 5 and describes the resource data as text, binary, comment, eof, and so on.

LaserWriter: How To Get Hardcopy Error Printouts

=====

This article last reviewed: 8 September 1988

Some users want to set the LaserWriter to print errors on a page rather than sending the message back to the host. Many of these users have heard that a variable in "errordict" needs to be changed, and have asked about the name of the variable.

Getting the LaserWriter to print errors is certainly possible, but it is not as simple as changing the value of a variable. Adobe Systems provides a PostScript program, "The Error Handler", that will do the job.

For more information, search under: Adobe Systems

LaserWriter II: Turns On Automatically To Redistribute Toner

=====

This article last reviewed: 8 September 1988

Every so often, the LaserWriter II sounds like it is starting to print, and then just stops. Needless to say, many users have inquired about this strange process.

In fact, it's only the LaserWriter II's way of redistributing the toner in the toner cartridge to ensure consistent, high-quality printouts.

Macintosh: How To Add On Serial Ports (10/94)

Revised: 10/12/94
Security: Everyone

Macintosh: How To Add On Serial Ports (10/94)

Article Created: 8 September 1988
Article Reviewed/Updated: 12 October 1994

TOPIC -----

How can I add serial ports to my NuBus equipped Macintosh?

DISCUSSION -----

To add serial ports to your Macintosh equipped with one or more open NuBus slots, both Apple Computer and Creative Solutions offer cards for the Macintosh.

- The Apple Serial NB card adds four serial ports which can be configured to operate at different speeds. The card can be installed in a Macintosh serving as a gateway to other networks, such as SNA with the SDLC protocol and X.25 with the HDLC protocol. This card is designed to be a platform for various serial communications applications (initially, MacAPPC and MacX25).
- The Creative Solutions Hustler and Hurdler HQS offer 2 and 4 additional serial ports respectively for use with modems or other serial devices.

For more information, search under "Serial NB card" or "Creative Solutions".

Article Change History:
12 Oct 1994 - Revised Serial NB card info, updated serial port vendor.

LaserWriter: How To Reset It Via PostScript

=====

This article last reviewed: 8 September 1989

The PostScript command:

```
systemdict begin quit end
```

resets the LaserWriter when connected to the LaserWriter in PostScript batch mode via AppleTalk.

This command removes the Laser Prep file, as well as any Postscript program that has been entered into the LaserWriter. A test page prints after the command has been executed -- if that option is turned on.

NOTE: To send the previous command, you MUST be in the PostScript batch mode of the PostScript interactive mode.

The following command can be used in ANY PostScript mode:

```
serverdict begin 0 exitserver  
systemdict begin quit end
```

LaserWriter IINT/NTX: Manual Correction For Clearing Paper Jam

Revised: 1/17/89
Security: Everyone

LaserWriter IINT/NTX: Manual Correction For Clearing Paper Jam

=====

This article last reviewed: 8 September 1988

On pages 91 and 92 of the LaserWriter IINT/IINTX User Manual (Apple part #030-3215-A) the user is instructed to open the printer to check for jammed paper. The user is then instructed to remove the cassette and pull out the paper.

The illustration shows the printer closed as the user is pulling out the paper. Although the instructions do not state to close the printer, the customer did and broke the toner cartridge.

The illustration is misleading. The printer should remain open until the cassette has been replaced.

LaserWriter IINTX SIMM: Specifications (8/95)

Article Created: 29 July 1988
Article Reviewed/Updated: 22 August 1995

TOPIC -----

This article describes the specifications for SIMMs used in the LaserWriter IINTX.

NOTE: This product has been discontinued and is no longer available.

DISCUSSION -----

Some of the vendors and vendors part numbers for the 64 pin SIMMs used on LaserWriter IINTX I/O boards are listed below. The SIMMs are 120 nanosecond RAM with CAS before RAS refresh.

256K SIMMs (64 pin)

Manufacturer	Vendor Part Number
TOSHIBA	TC511000-10
NEC	MC141

1 Megabyte SIMMs (64 pin)

Manufacturer	Vendor Part Number
HITACHI	HB56A000108AP1

Note that the SIMMs for the LaserWriter IINTX are different from the SIMMs used in CPUs.

SCSI Hard Disk Problem/Cure

Revised: 9/13/88
Security: Everyone

SCSI Hard Disk Problem/Cure

=====

This article last reviewed: 5 August 1988

PROBLEM:

When an external SCSI hard disk is connected to either a Macintosh SE or Macintosh II with an internal SCSI hard disk, neither hard disk is recognized by the system. When the external drive is disconnected, the internal hard disk works correctly.

Terms used in this article:

UUT = unit under test

CURE:

- 1) Does the system with the internal drive come up ok by itself and do diagnostics pass ok?

Yes -- Go on to Step 2

No -- Repair machine with normal diagnostic techniques and then retest configuration

- 2) Does the external SCSI device operate correctly on a Macintosh Plus, Macintosh SE with two 800Kb drives, or on the UUT when the internal SCSI cable is disconnected from the motherboard?

Yes -- Go on to step 3

No -- Repair external device using normal diagnostic techniques then re-test the configuration.

- 3) a) Fix or replace the SCSI address select switch on the external SCSI device
b) Fix or replace the SCSI Device select cable on the external SCSI device
c) Check or replace the external device's SCSI terminator.

Explanation: If the drives (internal and external) work independently of each other, chances are they conflict in one of two possible areas: Either there is

a SCSI address conflict or the SCSI buss is not terminated properly.

AppleFax Modem Problem/Cure

Revised: 4/26/89
Security: Everyone

AppleFax Modem Problem/Cure

=====

This article last reviewed: 5 August 1988

PROBLEM:

A Macintosh with the AppleFax Modem connected, the software loaded and another fax machine tries to dial in. On the AppleFax Modem station, the software asks the user if it should answer the phone. When the user selects "Answer Phone", the person at the AppleFax Modem hears the series of tones used to establish the connection between the two fax machines. The originator of the phone call still hears that the phone is dialing and that the destination AppleFax Modem HAS NOT answered the phone call.

CURE:

The problem above is caused when the telephone cable between the AppleFax Modem and the wall is plugged into the wrong RJ-11 jack, the one with the telephone icon below it, on the back of the AppleFax Modem. Plug the cable from the wall jack into the jack with the RJ-11 icon below it.

EXPLANATION:

There are 2 RJ-11 phone jacks on the AppleFax modem, one has an icon of a telephone and the other has an icon of an RJ-11 jack. Unlike other Apple modems the RJ-11 jacks on the AppleFax modem require that the telephone be plugged into the jack with the telephone icon and the line from the wall be plugged into the jack with the RJ-11 icon on it. The RJ-11 jacks are not interchangeable.

Apple IIC Plus: Specifications (Discontinued 11/90)

Revised: 10/7/93
Security: Everyone

Apple IIC Plus: Specifications (Discontinued 11/90)

=====

This article last reviewed: 13 September 1988

Here are specifications for the Apple IIC Plus:

CENTRAL PROCESSING UNIT (CPU)

- Microprocessor: 4 Mhz 65C02
- Clock Speed: 1 or 4 Mhz (user selectable -- press ESC key when you power the unit on)
- Address bus: 16 bits
- Address range: 65,536 bytes (64K)
- Data bus: 8 bits
- Registers (8 bit): accumulator, two index registers, stack pointer, and processor status register

MEMORY

- 128K of RAM (random-access memory), optionally expandable to 1.125 megabytes
- 32K of ROM (read-only memory), containing:
 - System monitor
 - AppleSoft BASIC interpreter
 - 80-column display firmware

TEXT DISPLAY MODES

- 80-column text (80 columns by 24 lines)
- 40-column text (40 columns by 24 lines)
- All text can appear on the screen as normal, inverse, flashing, or MouseText characters

GRAPHICS DISPLAY MODES

- Double high-resolution (560 dots horizontally by 192 dots vertically; 16 colors)
- High-resolution (280 dots horizontally by 192 dots vertically; 6 colors)
- Low-resolution (40 dots horizontally by 48 dots vertically; 16 colors)
- All graphics can be configured to allow four lines of text at the bottom of the screen.

KEYBOARD

- 63-key full-sized keyboard
- Full 128-character ASCII, including 96 uppercase and lowercase alphanumeric characters, and 32 control characters
- Special-purpose keys: shift, caps lock, control, escape, return, tab, delete, up arrow, down arrow, left arrow, right arrow, reset, open apple, option
- Keyboard is switchable between QWERTY and Dvorak layouts
- Includes volume slide control for speaker

DISK DRIVE

- Disk size: 3.5 inches
- Capacity: 800 kilobytes
- Recording surfaces: 2
- Tracks per surface: 80
- Blocks per disk: 1,600
- Push button for motorized eject

INTERFACES

- External disk drive port using 19-pin, D-style connector, allows a daisy-chain connection of up to three additional drives (Apple 3.5 Drive, UniDisk 3.5, and/or Apple 5.25)
- Two RS-232 serial ports with 8-pin minicircular connectors (for printer, modem, and other accessories)
- NTSC (composite) color video, via RCA phone jack
- 15-pin, D-style connector for video expansion
- 9-pin, D-style connector for mouse, joystick, hand controllers, or other accessories
- Internal, 34-pin connector for memory expansion up to 1.125 megabytes
- Standard, 3-pin grounded power plug

ELECTRICAL REQUIRMENTS

- Line voltage: 90 to 130 volts AC
- Line frequency: 50 to 60 hertz
- Maximum power consumption: 20 watts continuous
- Supply voltages:
 - +5 volts (+-5%)
 - +12 volts (+-10%)
 - 12 volts (+-10%)
- Maximum supply currents:
 - +5 volts=1.5 amps
 - 5 volts= 30 milliamps
 - +12 volts= 0.9 amps continuous -- 1.5 amps intermittent
 - 12 volts= 100 milliamps

ENVIRONMENTAL REQUIREMENTS

- Operating temperature: 50 to 104 degrees F (10 TO 40 degrees C)
- Relative humidity: 20% to 95%

SAFETY AND EMI QUALIFICATIONS

- FCC part 15 Class B Computing Devices
- UL 11 Office Appliances and Business Equipment

SIZE AND WEIGHT

..TIL03247-Apple_IIfc_Plus-Specifications_Discontinued_11-90.pdf

- Height: 2.5 inches (6.35 cm)
- Width: 12 inches (30.48 cm)
- Depth: 11.5 inches (29.2 cm)
- Weight: 7lb. (3.2 kg)

Included with the Apple IIfc Plus package:

- Apple IIfc Plus personal computer with built-in 800K disk drive
- Power cord
- Apple II System Disk
- Tutorial disk
- Owner's guide
- Apple II System Disk User's Guide
- A Touch of AppleSoft BASIC manual
- Limited warranty statement
- Packing list

GS/OS: Needs Latest ROM Revision To Work With ProFile

=====

This article last reviewed: 11 November 1988

When using GS/OS under Apple IIGS System Disk 4.0 with a 5MB ProFile, be sure you are using the latest ProFile ROM revision.

A 5MB ProFile needs the 341-0299 ROM revision to work correctly with GS/OS.

If you have problems formatting, or receive a message stating that your drive appears to be damaged, you need the new ROM.

(NOTE: This ROM is a service part, and is located on the Apple II price pages.)

Apple SuperDrive: Using And Formatting Disks

Revised: 8/22/91
Security: Everyone

Apple SuperDrive: Using And Formatting Disks

=====

Article Created: 16 September 1988
Article Last Reviewed: 22 August 1991
Article Last Updated: 22 August 1991

TOPIC -----

This article tells the proper way to format Apple SuperDrive disks, and the precautions to take in using them.

DISCUSSION -----

Although the Apple SuperDrive (formerly Apple FDHD) supports both the Group Code Recording (GCR) and Modified Frequency Modulation (MFM) formats, the 1.4MB format requires that you use only Apple SuperDrive disks.

These disks have a special thin recording surface that allows the higher data rates. You CAN still use 800K disks, but they will only format as 400/800K disks. Apple SuperDrive media are identifiable by the 2 holes on the disk -- one on the upper left, the other on the upper right. The bonus hole in the upper left looks like an extra write-protect notch.

The SuperDrive disks will only format to 1.4MB. The drive will sense if a high-density disk is inserted.

Don't use these disks in older 800K disk drives: if you format the disk in an 800K drive, it will not work in the SuperDrive. The drive will try to read in MFM mode when it notices the bonus hole in the media, and then ask if you want the disk formatted. There is no option in the dialog box to format to any other size.

GS/OS: Correction To Formatting Options Error In The Manual

Revised: 9/22/89
Security: Everyone

GS/OS: Correction To Formatting Options Error In The Manual

=====

This article last reviewed: 14 September 1988

The Apple IIGS System Disk Users Guide, (Apple Part #030-1495-B) has an error on page 47.

The first paragraph on page 47 SHOULD read:

"The format options for 3.5-inch disks are 800K 2:1, 800K 4:1, and 400K 2:1. 800K and 400K refer to the capacity. 2:1 and 4:1 refer to different layouts of tracks and sectors on a disk. Choose 800K 2:1 for ProDOS 16 or GS/OS files and 800K 4:1 for ProDOS 8 files (or for a combination of ProDOS 8 and Macintosh files). The only time you should choose 400K is if you're using a single-sided 3.5" disk. The format option for 5.25-inch disk is 140K."

The essential (and correct) information in the new paragraph is:

When using ProDOS 8, select a 4:1 layout and ProDOS 16 and GS/OS should use a 2:1 layout.

Macintosh IIX: General Description (Discontinued)

Revised: 6/7/94
Security: Everyone

Macintosh IIX: General Description (Discontinued)

Article Created: 16 September 1988
Article Reviewed/Updated: 17 July 1992

TOPIC -----

This article describes the Macintosh IIX.

DISCUSSION -----

The Macintosh IIX computer is a modification of the Macintosh II design that uses a Motorola MC68030 microprocessor and a MC68882 numerics coprocessor. The Macintosh IIX uses the new Apple SuperDrive (formerly Apple FDHD) 1440K floppy drive. Upgrades for the Macintosh II will be available for both the drive and the logic board.

MC68030

The Macintosh IIX uses the Motorola MC68030 at 15.6672 MHz, the same speed as the existing Macintosh II. The MC68030 is Motorola's second-generation 32-bit microprocessor, and combines a central processing unit, a data cache, an instruction cache, an enhanced bus controller, and a memory management unit into a single VLSI device. Internal function blocks of the microprocessor are designed to operate in parallel, allowing instruction execution to be overlapped.

The MC68030 integrates the functionality of the MC68020 32-bit microprocessor with a subset of the MC68851 Paged Memory Management Unit (PMMU). Commonly called the 030 (pronounced "oh-three-oh"), the MC68030 is compatible with Macintosh II timing and software.

MC68882

The MC68882 numerics coprocessor (also called the Floating Point Unit, or FPU) provides high speed, extremely accurate floating point computation to

IEEE standards.

The processor operates in parallel with the MC68030, and is clocked at 15.6672 MHz using the same clock signal as the MC68030. Calls to the Apple SANE routines will use the MC68882. The MC68882, also called the 882 (pronounced "eight-eighty two"), is pin- and electrically-compatible with the MC68881 coprocessor in the Macintosh II.

Both processors use the same base instruction set -- the major advantage of the MC68882 is increased speed. With the MC68882, you can perform both memory moves and chip operations in parallel -- as long as they don't conflict -- thus boosting floating point performance by about 15%.

Memory Management

Macintosh IIX can support the A/UX operating system without adding the PMMU, thanks to on-chip memory management by the MC68030. The MC68030 allows true 32-bit address translation with hardware page replacement. The built-in memory unit is also capable of ignoring the high 8-bits of the address to allow Macintosh software to run in 24-bit mode.

(NOTE: The MC68030 PMMU is a subset of the MC68851 PMMU, rather than an exact replacement.)

Wait States

- The Macintosh IIX uses one wait state to access the RAM.
- The Macintosh II has two wait states, one for RAM, and one for the HMMU or PMMU.

Given the CPU clock speed, you need one wait state to make sure you read from RAM at 120ns. The 15.6672 clock frequency has an active period of 63.8276ns. If the CPU reads without wait states, you would need 60ns RAM. Given the limited availability of these 60ns chips, Apple has chosen one wait state and 120ns RAM chips.

Apple SuperDrive (formerly Apple FDHD)

The Apple SuperDrive can read and write to any of the major 3.5-inch disk formats, including Macintosh (GCR 400K, 800K, and MFM 1.44MB), Apple II (800K), MS-DOS and OS/2 (MFM 720 and 1.44MB).

GCR stands for Group Code Recording; MFM stands for Modified Frequency Modulation. MFM and GCR only effect how the bits are placed on the disk, not the directory structure. The drive is supported by the SWIM (Sander, Woz Integrated Machine) chip.

(NOTE: There is special 1.44MB media that should NOT be used in the older 400K or 800K drives.)

SWIM Chip

The SWIM chip is a single-chip combination MFM/GCR controller for internal and external floppy drives. It was designed for the SuperDrive, but is compatible with the current 400K and 800K drives. The SWIM chip replaces the IWM chip, and is pin- and function-compatible with that device.

Apple IIGS System Software 4.0: GS/OS General Information

Revised: 9/22/89
Security: Everyone

Apple IIGS System Software 4.0: GS/OS General Information

=====

This article last reviewed: 14 September 1988

The heart of Apple IIGS System Software 4.0 is GS/OS, the first 16-bit, native-mode operating system written in 65816 code.

GS/OS significantly speeds up boot time, disk access time, and program launch time, and increases the performance of disk-intensive applications. GS/OS is file system independent. Applications that make GS/OS calls will be able to read and write many different and seemingly incompatible file systems.

An added benefit is the ability to access file systems that support very large files and storage media (up to 4 gigabytes). GS/OS is compatible with Apple IIGS ProDOS 16, and will run applications that follow ProDOS 16 design guidelines.

Apple IIGS System Software 4.0 contains two disks:

SYSTEM.DISK
SYSTEM.TOOLS

There are also two new manuals:

Apple IIGS System Disk User's Guide
Apple IIGS System Tools

The user's guide explains the Finder. The System Tools manual explains the programs on the SYSTEM.TOOLS disk.

System Requirements:

A 512K Apple IIGS System with ROM revision #01 is required to run System Software 4.0. On system-boot, the first revision of the Apple IIGS ROM displayed "Apple IIGS" at the top of the screen with nothing at the bottom. The rev 01 ROM displays "Apple IIGS" at the top with copyright and "ROM rev" at the bottom.

The INSTALLER

The Installer is a new program for installing files on your startup (boot) disk. The Installer is located on the SYSTEM.TOOLS disk along with the other utility programs.

The Installer allows users to update System Files without having to drag files to the correct location in the System Folder. The SYSTEM.DISK contains a minimum set of files the "standard user" will need to be able to operate. If you want support for the following products and programs, you MUST run the Installer:

- Apple 5.25" Disk Drives
- UniDisk 3.5" Disk Drives
- SCSI Hard Drives
- AppleCD SC (High Sierra)
- ImageWriter LQ
- LaserWriter
- AppleTalk ImageWriter or AppleTalk ImageWriter LQ
- Apple MIDI Interface
- Epson Printer
- Chooser II
- Namer II
- Advanced Disk Utility

The Installer program runs like the Font/DA mover on the Macintosh. If you do not run the Installer to add support for connected device, it will not be accessed while running GS/OS -- for example, if an Apple 5.25" disk drive is connected, it will not show up in the finder or while running applications until the Driver file is installed.

NOTE: When using the Installer, make sure you do not remove any files from the Apple IIGS SYSTEM.DISK or SYSTEM.TOOLS disks. Both disks are needed to update other disks. The tool files are located only on the SYSTEM.DISK and AppleTalk Utilities are located only on the SYSTEM.TOOLS disk.

File System Translators

GS/OS uses a generic file interface that communicates with applications. This operating system uses a File System Translator (FST) that acts as an

intermediary between GS/OS and the specific file system and device. ProDOS and ISO/High Sierra FSTs are included with GS/OS.

This organization will allow GS/OS to read many different kinds of disks (only two are supported at this time). Some file systems may have calls that are not supported by GS/OS; for example a hard drive with tape backup may have a command to backup the volume to tape. Moreover, some FSTs can not support all of the GS/OS calls. The High Sierra FSTs do not permit write calls because CD-ROM is a read-only medium.

Advanced Disk Utility

The Advanced Disk Utility lets you divide hard disks into multiple volumes, called partitions. You can use the Advanced Disk Utility to initialize, erase, and zero hard disks, partitions of hard disks, 3.5" disks, 5.25" disks, and RAM disks. All of the functions, except partitioning and zeroing a disk, can be done at the Finder level.

Partitioning

The Advanced Disk Utility partition option has more options than the partition program supplied with the SCSI card. To support SCSI devices you must have the SCSI ROM revision installed, ROM part # 341-0437-A.

The new features are:

- Initialize partitions on the same hard drive with different file systems
- Up to 7 partitions per hard drive, but total of 7 partitions can be accessed for each SCSI card, regardless of the slot the SCSI card is in.
- Uses the full 80MB on an 80MB hard drive (3 partitions).

Zeroing

Zeroing a volume wipes out everything on the volume. Unlike erasing, zeroing removes not only the volume directory, but also all the files, the file system, and even tracks and sectors. After zeroing, a volume must be initialized again before it can receive data. Zeroing writes over all the data, so no one can reconstruct the information that was contained on the drive.

GS/OS: Why It Causes UniDisk 3.5" Drive Motor Noise

=====

This article last reviewed: 14 September 1988

When using a UniDisk 3.5" with GS/OS you will notice something different: the drive light will flash about 2 times per second, and the motor will seem to be starting up. (With the more familiar ProDOS 16, the light flashed but the motor did not behave in this fashion.) This seemingly odd behavior is caused by a new feature of GS/OS.

GS/OS lets the application know when a disk is ejected or switched from the drive. In order for GS/OS to check for disk switch events it sends a small program to the controller located in the UniDisk 3.5". When this program executes, the UniDisk 3.5" get ready for a disk access, causing the drive light to turn on and start up the motor.

The disk switch event allows the application to check the drive before it writes out information and changes the directory. This change also allows the DISK CACHE desk accessory to function correctly with the UniDisk 3.5.

Macintosh II: How To Simultaneously Access AppleShare And UNIX

Revised: 6/29/90
Security: Everyone

Macintosh II: How To Simultaneously Access AppleShare And UNIX

=====

This article last reviewed: 24 August 1988

It is possible for a Macintosh II to have simultaneous access of an AppleShare file server and a UNIX machine. There are two ways to go about this.

The first way is to use K-Term and K-TALK/Host software. K-Term provides a multi-window terminal emulator for the Macintosh. With it, a single Macintosh can emulate as many as four terminals for any UNIX host computer running K-TALK/Host via the same LocalTalk cable. By making AppleTalk protocols available to the UNIX system, this software makes it possible for the UNIX system to communicate with AppleTalk devices.

Important: To run K-Term and K-TALK/Host softwares, the Kinetics FastPath gateway box is required between the UNIX machine and AppleTalk.

The second way is to combine UNIX and LocalTalk with NCSA Telnet 2.2 software. This package provides interactive access from a Macintosh II to Telnet hosts on TCP/IP networks. The hardware configuration requires a Macintosh connected to AppleTalk and a Kinetics FastPath that connects AppleTalk to Ethernet.

Note: Telnet is public domain software from The National Center for Supercomputing Applications at The University of Illinois at Urbana-Champaign.

A/UX: How To Recover dev/syscon

Revised: 9/18/92
Security: Everyone

A/UX: How To Recover "dev/syscon"

=====

Article Created: 15 September 1988

Article Change History

08/31/92 - REVIEWED

- For technical accuracy.

08/31/92 - Updated

- Removed obsolete information.

TOPIC -----

This article discusses what happens when the "dev/syscon" file is corrupted and two ways to recover.

--- problem description -----

On system startup, the system went to the point where it checks the total amount of memory and hung. It didn't get to the point where it asks if a check of the file system should be made.

Running "esch -v" returned the system messages:

```
Running autorecovery esch -v
fscheck - dev/dsk/c5d0s0
```

The system completed phases 1, 2, and 3 of the file system check with no problems. Then, in phase 4, it found problems:

```
free inode count wrong and superbk -- fixed
file system modified
```

It went through a few other file systems. Then, in the section where A/UX starts validating the files, it showed a permissions error on major/minor device number. Then, it showed replacing "/dev/syscon".

It started validating other files. Then, it bombed leaving these messages:

```
/dev/syscon was not replaceable
exiting file check.
```

After this, you cannot get his kernel up and running nor can you launch on "/newunix".

DISCUSSION -----

Most likely, the "/dev/syscon" file was corrupted. There are two ways you might be able to recover it from SASH:

Here are the two ways:

- a. Directly copy /dev/syscon from one of the Eschatology partitions.

For example:

```
pname -s 3 "Eschatology 1"
rm -f /dev/syscon /dev/console /dev/systty
cp (0,0,3)/dev/syscon /dev/syscon
ln /dev/syscon /dev/console
ln /dev/syscon /dev/systty
```

- b. Create /dev/syscon from scratch.

```
rm -f /dev/syscon /dev/console /dev/systty
mknod /dev/syscon c 7 0
chmod 722 /dev/syscon
ln /dev/syscon /dev/console
ln /dev/syscon /dev/systty
```

Note that "/dev/console", "/dev/syscon", and "/dev/systty" are all hard-linked.

AppleFax Modem: It Waits 2 Minutes After A Call To Disconnect

=====

This article last reviewed: 13 September 1988

Some people have asked why the AppleFax modem seems not to disconnect automatically if the modem was dialed accidentally from an outside line (for example, a wrong number).

Although the caller has hung up, the modem does not immediately disconnect.

The AppleFax modem eventually DOES time out and disconnect. However, the timeout does not occur until 2 minutes into the "no modem found" condition.

Apple Scanner: Fixing Save As Untitled Settings 2 Problem (9/95)

Article Created: 16 September 1988
Article Reviewed/Updated: 20 September 1995

TOPIC -----

Whenever I scan and save a new image and then I try to save the resulting new settings I get a System Error ID 12. What is wrong?

DISCUSSION -----

In the AppleScanner software, the brightness and contrast settings can be saved. Each setting that is saved has to be named; the default name is "Untitled Settings".

If the settings are saved as "Untitled Settings", the next default name is "Untitled Settings 2". The problem occurs when saving these new settings as "Untitled Settings 2": when an image is scanned and saved, a System Error ID 12 occurs.

The reason for the error is that maximum length for a setting name is 16 characters, and "Untitled Settings 2" violates this rule.

To work around this problem, each time a new setting is saved, use the "Save as..." option, and give the file a name of 16 or fewer characters.

PC Transporter: IIGS Driver Not Available For AppleShare

=====

Article Created: 16 September 1988
Article Last Reviewed: 27 January 1992
Article Last Updated: 27 January 1992

TOPIC -----

Can I use PC Transporter with an AppleShare File Server?

DISCUSSION -----

Applied Engineering's PC Transporter, the MS-DOS card for the Apple II family, can theoretically work with the AppleShare File Server. Specifically, you can use the server as drive "D" when using the MS-DOS software, as well as Apple IIGS mode.

However, such a driver that can access the AppleTalk resources of the Apple IIGS doesn't currently exist. Development of the driver is typically the responsibility of the card's manufacturer.

On AppleLink, you can find contact information for the various vendors by clicking the Library Index button to view the folder structure in the Tech Info Library. An alphabetic listing of vendors is in the Third Party Company Directory folder.

ProDOS Applications Need "Chooser II" To Select A Printer

=====

This article last reviewed: 13 September 1988

Some users running AppleShare networks have had problems getting the ProDOS applications to print.

To get a ProDOS application to print correctly, you need to run the "Chooser II" program, which is in the AppleTalk folder on Apple II Workstation disk. This program allows you to select a printer.

(NOTE: If the printer selected is a LaserWriter, the ImageWriter emulator is downloaded immediately. "Chooser II" can run from either the server or the work-station. Ensure that the application is printing to slot 7. If printing to a LaserWriter, set up the program for printing to an ImageWriter.)

LaserWriter II: Front Panel Light Explanation

=====

This article last reviewed: 19 September 1988

The front panel lights will act differently depending on the type of the controller board installed in the LaserWriter II. Each of the 3 controller boards, the IISC, NT, and NTX, will produce different displays.

With the printer operating correctly, turn the printer ON. After the user print comes out, open the cover wait 10 seconds, and close the cover. Each of the LaserWriter II controller boards will act differently. The following chart show how each of the boards react.

LaserWriter IISC - ALL THE LIGHTS GO OFF. After closing the cover the READY light comes ON.

LaserWriter IINT - ALL THE LIGHTS GO OFF and TONER light comes ON solid. After closing the cover the READY light comes ON, and the TONER light stays ON. But after printing a document the TONER light goes OFF.

LaserWriter IINTX - ALL THE LIGHTS GO OFF and TONER light comes ON blinking. After closing the cover READY light comes ON, and the TONER light goes OFF.

LaserWriter II: Multiple Paper Feed Problem/Cure

Revised: 1/17/89
Security: Everyone

LaserWriter II: Multiple Paper Feed Problem/Cure

=====

This article last reviewed: 19 September 1988

SYMPTOM: Multiple pieces of paper are being fed into the printer, eventually causing a paper jam to occur.

CURE: The paper feed roller assembly and/or the transfer guide assembly may be defective.

Replace the paper feed roller assembly (971-0017) first, if this does not solve the problem replace the transfer guide assembly (971-0019). Replacing the parts rather than fixing them is the best way to do it. Remember that a defective motor (971-0014) or gears could also exaggerate the problem.

ADDITIONAL INFORMATION:

The paper feed roller assembly (971-0017) is feeding the page to the transfer guide assembly (971-0019) and then paper feed roller should stop. The transfer guide assembly should align the page and then feed through. At the time when the transfer guide assembly is feeding the page the paper feed roller should return to home position. If the paper feed roller is defective (roller itself or clutch are bad) the timing will be off and the paper feed roller will attempt feeding second page. When the transfer guide assembly is slippery or defective it will cause a slight delay in the paper transfer causing paper jam.

LaserWriter II: Excess Toner Spilling Inside

Revised: 1/17/89
Security: Everyone

LaserWriter II: Excess Toner Spilling Inside

=====

This article last reviewed: 19 September 1988

Symptom: After repair the LaserWriter II will spill excess toner during printing into the body of the LaserWriter II.

Cause: This is caused by a loose or missing screw that attaches the high voltage power supply to the chassis in the area where the capacitor is mounted to the chassis through the chassis lug. The missing screw prevented proper grounding of the high voltage power supply to the LaserWriter II chassis.

Additional Information:

The printer was initially repaired for a lack of printout. The high voltage power supply was found to be defective. When the high voltage power supply was replaced the LaserWriter II started spilling toner badly during printing. While the printer was properly diagnosed, during re-assembly a screw in the high voltage power supply mounting was not re-installed. This caused a bad ground connection for the high voltage power supply which caused excess toner to be dumped from the cartridge.

LaserWriter IINTX: Emulating The HP LaserJet's Printer Language

Revised: 9/22/89
Security: Everyone

LaserWriter IINTX: Emulating The HP LaserJet's Printer Language

=====

This article last reviewed: 24 September 1988

Some users of LaserWriter IINTX have asked: what is "PCL", and how is it different from PostScript and LaserJet?

PCL is an acronym for Printer Control Language, and is the language on which the HP LaserJet Plus is based. PCL lacks the overall power of PostScript, but is adequate for standard printing needs.

Apple's emulation of the HP LaserJet Plus is not perfect. Pages 118 and 119 of the LaserWriter IINT/NTX Owner's Guide (Apple Part #030-3215-A) explain the differences.

Because we do not emulate PCL perfectly, you may encounter some problems with certain applications -- for instance, if you send the Hewlett Packard PCL command to reset LaserJet Plus to LaserWriter IINTX while in LaserJet emulation mode, the system may crash.

We strongly suggest that you test a LaserWriter IINTX in a PCL environment before making a decision to go with this type of setup.

LaserPrep And PostScript: Solution To Interpreter Problem

Revised: 9/29/88
Security: Everyone

LaserPrep And PostScript: Solution To Interpreter Problem

=====

This article last reviewed: 9 September 1988

There is a problem with Apple LaserPrep that surfaces on later versions of PostScript interpreters (version 5.0 and newer). The symptoms are generally that no error messages are generated and that no output is produced.

The newer versions of the LaserPrep implements a number of smoothing functions that are present in some versions of Postscript interpreters. The LaserPrep header checks for the existence of these functions in the interpreter. If it finds that such funtions exist, it disposes of the code for these functions (the code is the hexadecimal at the end of the file).

Unfortunately, when hooked up serially, the LaserPrep disposes of code until it reaches a Control-D, which ends up being the end-of-job marker at the end of the users PostScript file. Hence, the body of the job gets thrown away along with the rest of the header.

On a laser printer where these functions don't exist, the code is used, and the LaserPrep should function correctly.

A quick way of determining whether the Macintosh PS file needs this version of the LaserPrep file is to check the first line, which should read:

```
!PS-Adobe-2.0
```

Other versions have different headers and use different LaserPrep file version numbers.

The solution to this LaserPrep problem is two-fold.

- (1) If you are not using the code (that is, if you have something like a QMS printer), then you can delete the code entirely. This has the advantage of making the LaserPrep file smaller and thus quicker. The disadvantage is that if you add devices that don't have the built-in functions, you will have to either use two different version of the LaserPrep file, or revert

to the second method.

- (2) The second method consists of a very small change in the LaserPrep code so that the laser printer will always use the smoothing code. This may not be very efficient, but it guarantees that the code should work for most Postscript devices.

The solutions that follow concern Apple LaserPrep file version 68, generated by LaserWriter driver version 5.2. Which modification you use depends on which solution you prefer.

Solution #1:

Delete everything from the line shown below, to the end of the header file. This line is the last line of text immediately preceding the first section of hexadecimal code (if you are using MacWrite to view the PostScript file, it's about 12 pages in). The end of the header file can be located by finding the line that says "%EndProcSet". Do not delete the "%EndProcSet" line. It must remain to indicate the end of the header.

```
currentfile ok userdict/stretch known not and{eexec}{flushfile}ifelse
```

Solution #2:

Change the line located just above the first set of hexadecimal codes from:

```
currentfile ok userdict/stretch known not and{eexec}{flushfile}ifelse
                                to
currentfile ok userdict/stretch known not and pop
true{eexec}{flushfile}ifelse
```

Locate a second line of text after the long series of zeros, which follows the first section of hexadecimal codes, and immediately before another section of hexadecimal code.

Change the line located just above the second set of hexadecimal codes from:

```
currentfile ok userdict/smooth4 known not and{eexec}{flushfile}ifelse
                                to
currentfile ok userdict/smooth4 known not and pop
true{eexec}{flushfile}ifelse
```

LaserWriter Driver 5.1 will generate header files with a version number of 65. Earlier driver versions will have smaller numbers. This information should remain good as long as the second line of the actual PostScript file reads %! PS-Adobe-2.0., as described above. If this version number changes, the location of the lines to be changed may also differ, and there may be other lines that need to be changed as well.

If UNIX, or A/UX, is used to look at these Command-K generated PostScript files, the facility exists to number the lines of the file. The two lines that need to be changed are 487 and 534.

Macintosh II: System Error 25 When Using Three Or More Monitors

=====

Article Created: 20 September 1988
Article Last Reviewed: 30 June 1992
Article Last Updated:

TOPIC -----

If you are using three monitors with your Macintosh II (for instance, a LaserView, an Apple RGB, and a SuperMac monitor), you may receive a System Error 25.

DISCUSSION -----

This is an out-of-memory error. When using three or more monitors, you need to ensure that the applications have enough memory to support three screens worth of data and word processing cut, copy, and paste functions.

If you use MultiFinder or System 7, you need to increase the amount of memory for each application. If you run on a 1MB system, you need to remove anything that uses extra memory. You should also switch to the lowest bits/pixel possible (two).

(NOTE: The LaserView in particular uses a lot of system memory when it is running in "high" mode. This, coupled with using two additional monitors, may be the root of the problem.)

Suggestions On Connecting More Than 254 Macintoshes to Ethernet

=====

This article last reviewed: 20 September 1988

If you want to connect Macintoshes together in a large network -- BEYOND the AppleTalk 254 node limit on Ethernet, for instance -- here a couple of suggestions:

1. Do not connect all of the Macintoshes directly. Use a LocalTalk network and FastPaths to bridge the LocalTalk Macintoshes onto the Ethernet.
(This is a low-end solution.)
2. Use two FastPaths linked together with LocalTalk cabling to slow the packets to LocalTalk speed, 234K baud. This method creates two separately addressable zones with 254 AppleTalk nodes per zone.

=====

This article last reviewed: 16 August 1990

Theoretically, there are several ways for Macintoshes to communicate with a Xerox 6085, including over AppleTalk. This article examines three communications methods:

- Xerox 6085 Ethernet connection
- "Kid" from Interpreter, Inc.
- The Xerox 6085 serial-port direct connection

Xerox 6085 Ethernet Connection

The best solutions take advantage of the Xerox 6085 Ethernet communications ability. The Xerox 6085 with Ethernet installed can use ViewPoint NetCom Xerox software to provide Ethernet access. This package contains user authentication, and access to functions such as electronic printing, filing, and mailing. The communication protocol may be either TCP/IP or XNS.

With TCP/IP, files are transferred using a FastPath from Kinetics, which connects the Macintosh and LocalTalk to Ethernet. FastPath, in conjunction with NCSA (National Center for Supercomputer Applications) Telnet software, provides direct log on, directory listing, and file downloading capabilities within the FTP support. NCSA Telnet is available on Internet through subscription to Bitnet, ARPANET, CSNET, and also directly from the University of Illinois.

If TCP/IP is not available, XNS support is available through a 3COM3 server. This requires that the Macintosh can talk to the server over AppleTalk and that the Xerox 6085 can talk to the server over XNS. Each, then, may be able to access one another's files once they have been uploaded to the server. Although often asked for, XNS is not directly supported by the Macintosh.

"Kid" from Interpreter, Inc.

Kid uses a conversion utility that writes Xerox 6085 files to 5.25-inch DOS disks. The files can be written to and read from PC software packages, like Microsoft Word, WordStar, and MultiMate. These PC disks are placed in an Apple 5.25-inch drive. Using AFE (Apple File Exchange) software, you can mount PC disks. Once mounted, you can read and convert PC-formulated files to Macintosh formats.

The Xerox 6085 Serial-port Direct Connection

The Xerox 6085 system can communicate through its serial port. One option is to send serial information from the Xerox 6085 through this port to the Macintosh, or vice versa. This method represents a low-end connectivity.

For more information, search under: "National Center for Supercomputer Applications" and "Interpreter, Inc."

AppleFax: How to Save Microsoft Word 3.0 (.01,.02) Files to Disk

=====

This article last reviewed: 21 September 1988

If you get the proper AppleFax modem print dialog box from within Microsoft Word 3.0 (by holding down the shift key), but cannot save the Microsoft Word file to send with the AppleFax application, you may need to select "Print" a second time.

Microsoft Word 3.0 may require selecting the "Print" menu item a second time to have the AppleFax file written to disk.

When "Print" is shift-selected the first time, a dialog box labeled "AppleFax Resource" appears, with "Save As" as an option in the dialog box. However, pressing the "Save As" button does NOT save the AppleFax file.

When "Print" is shift-selected a second time, a dialog box labeled "Printer: AppleFax Modem" appears. Clicking "OK" in this dialog box DOES write the file to disk.

(NOTE: Normally, after changing printing resources the "Page Setup" menu item should be selected and clicked "OK". With Microsoft Word 3.0, shift-select the "Page Setup" item.)

HyperCard: How To Restrict User To Browse While Modifying Stack

=====

This article last reviewed: 21 September 1988

If you want to restrict the user of your HyperCard stack to the browse level while the script is allowed to modify the stack, take note of the following scripts:

1. This script stores the Home card userLevel in the global variable "Store_userLevel" and sets the userLevel to 1 (Browsing). When quitting the stack, you may restore the userLevel to the value in "Store_userLevel".

```
on openStack
  global Store_userLevel
  put the userLevel into Store_userLevel
  set the userLevel to 1
end openStack
```

2. This script shows how to change the userLevel, so modifications can be made to the stack via HyperTalk commands.

```
on mouseDown
  set the userLevel to 5
  -- (Do stack modifying commands here)
  set the userLevel to 1
end mouseDown
```

3. This script shows how to use the "cantmodify" property to prevent a user from modifying a stack while still allowing the script to do so.

```
on openStack -- (Put this in the stack script)
  set cantModify to true
end openStack
```

```
on mouseDown
  set cantModify to false
```

```
-- (Do stack modifying commands here)
set cantModify to true
end mouseDown
```

HyperCard: Workaround For cantModify Stack To Free Disk Space

Revised: 11/2/88
Security: Everyone

HyperCard: Workaround For "cantModify" Stack To Free Disk Space

=====

This article last reviewed: 21 September 1988

If you have a HyperCard stack that is over 700K, you may have experienced this problem: when the stack is opened, it creates 100K or more of free space, thus exceeding the disk memory capacity.

Normally, a HyperCard stack does not take additional disk space on opening. You may find, however, that there is an "on openXXXXX" (XXXXX = Card, Field, etc.) script in the stack that causes additional disk space to be used when the stack is opened. Also, any change to the stack causes it to take up more room unless it is locked via the Finder.

ImageWriter LQ: Use Geneva or Helvetica for Faster Quality Print

Revised: 10/18/88
Security: Everyone

ImageWriter LQ: Use Geneva or Helvetica for Faster Quality Print

=====

This article last reviewed: 7 October 1988

A problem has appeared with the ImageWriter LQ when set for Faster Quality. For example, when printing a half-page document from WriteNow in Best Quality, either bidirectionally or unidirectionally, the print looks good. However, when printing in Faster Quality, either bidirectionally or unidirectionally, the print quality is poor, jagged, and hard to read. Except for the spacing, Draft Quality is more readable than Faster Quality. These results are quite different than when using the ImageWriter II driver.

The problem arises from the fact that Faster Quality was designed to be the quickest way to print both graphics and text in the WYSIWYG format. In the Faster Quality mode of the ImageWriter LQ, the typeface used is essentially the screen font in bold face. Test results show that 12-point Times in Faster Quality is not the most readable font. Using other fonts in 12-point and Faster Quality, like Geneva or Helvetica, improves readability.

A/UX: Compatible Third-Party Office Productivity Tools (9/94)

=====

Article Created: 18 October 1988
Article Reviewed/Updated: 12 September 1994

TOPIC -----

This article describes several third-party office productivity tools that are compatible with A/UX.

DISCUSSION -----

SoftQuad

SoftQuad Publishing Software is an automated, batch text and graphics formatter. it includes tools for the creation of complex tabular material, mathematics, graphs, and charts. Its major strength is the creation of long documents on laser printers and typesetting machines. SoftQuad Publishing Software provides all the capabilities required for high-end production publishing: automatic kerning, hyphenation using a special dictionary, capacity for multiple columns, English-language names for macros and commands, simple tools to create new macro-formatting packages and support for spot color separation.

Arrc (formerly STARx)

STARx Pharmacy package assists pharmacists faced with expanding administrative, legal, and patient care demands. STARx automatically maintains patient records as required by state and federal governments. STARx also handles automatic generation of prescription labels, maintains drug inventories, and performs all accounting functions necessary for billing insurance companies and state welfare systems. A customized STARx network, layered on top of A/UX, creates a specialized communications group consisting of STARx, its retail pharmacies, drug wholesalers, insurance companies, and state agencies, and in-house departments.

Abacus Concepts

Statview II, now running under A/UX, features interactive data analysis and presentation quality graphics. Statview II brings the graphics Macintosh interface to the UNIX users, providing them with Macintosh ease of use. Statview II includes a complete statistical analysis package and a comprehensive drawing environment. With these, users can build high-quality charts and graphics directly from their data and analyses.

Uniplex Integration Systems Inc. (formerly Uniplex Distribution Inc.)

Uniplex offers two packages: Uniplex II Plus and the Uniplex Advanced Office System. Uniplex II Plus is the center of Uniplex Business software for Macintosh II and A/UX. It includes a fully-integrated word processor, spreadsheet, and relational database manager plus screen- and menu-building features.

The Uniplex Advanced Office System handles inter- and intra-office data communications. It includes a time manager, personal organizer, card index, report writer, and electronic mail.

Other products known to exist at one time or another are: Goldmedal by Decathlon; MacNix/A by LIST/spA; R Systems suite of software; WingZ by Innovative Software.

To locate a vendor's address and phone numbers, use vendor name as a search string.

DISCUSSION -----

Alsys

The Alsys ADA Compiler for A/UX is a complete production-quality implementation of ADA, suitable for demanding ADA developments. Features of the Alsys ADA compiler include: suitability for large applications, accuracy and reliability, multi-library environment, tool support, and much more.

Franz Inc.

Franz Incorporated's Allegro CL, an extended, common LISP, broadens the scope of problems that minicomputers can address. Allegro CL and A/UX transform the Macintosh II into an ideal delivery vehicle for artificial intelligence applications and standard applications with embedded AI technology. For example, using Allegro CL, A/UX programmers can add sophisticated advisory and analysis components to applications already running under A/UX.

Unisoft

Unisoft offers three compilers: Optimizing C, Optimizing FORTRAN, and

Optimizing Pascal. Unisoft has implemented these compilers specifically for A/UX and the Motorola 68000 series architecture. The compilers can maximize the power offered by the Macintosh II computer by increasing the program execution speed by as much as four times, performing global optimizations previously available only on super-minicomputers or mainframe computers. The Unisoft compilers have been optimized for the Motorola 68020 and 68881 floating point chips and feature one-pass compilation for maximum extensions.

Absoft

RAT FORTRAN is a mainframe-caliber compiler for program development on the Macintosh II. It conforms completely to ANSI X3.9-1978, IEEE P754, and MIL-STD 1753 specifications. It also includes several extensions from the proposed FORTRAN 8X standard and several features to facilitate porting programs from the VAX environment. The A/UX version provides full support for the Macintosh Toolbox and is completely compatible with the A/UX environment and all of its support tools. RAT FORTRAN also handles inter-language calling with C.

Macintosh: Do Not Draw Power Directly From The Power Supply

=====

Article Created: 28 September 1988

Article Change History

9/15/92 - REVIEWED

- For technical accuracy.

TOPIC -----

Can I draw power directly from the Macintosh power supply?

DISCUSSION -----

Due to design constraints, you should not draw power directly from the Macintosh power supply.

Use an additional power supply to generate the necessary DC voltages for any peripherals or accessories, such as non-standard hard drives or fans. Thermal considerations are important as well.

(NOTE: As with all non-Apple hardware modifications or upgrades, such adjustments will void the computer system's warranty.)

Weather Forecast Display System: BBC Uses Macintosh & PaintBox

=====

This article last reviewed: 22 September 1988

In Britain, the BBC (British Broadcasting Corporation) uses a Macintosh II to control a Quantel PaintBox for national weather forecasts. (The development started on the Lisa and was converted to the Macintosh.) They also use Macintoshes to gather weather data from various places around the country.

The software shows a detailed map of the UK and Europe. They drag standard icons onto the maps, including storm clouds, snow clouds, and (on some rare days) the sun. They also can enter temperatures on the map.

The PaintBox is used to add color, and the forecaster pushes a button to advance from one frame to the next.

For more information, contact the BBC directly in London at Broadcasting House.

Jolly good show, BBC!

LaserWriter: Clear Manually-Downloaded Fonts At End Of Print Job

Revised: 10/27/88
Security: Everyone

LaserWriter: Clear Manually-Downloaded Fonts At End Of Print Job

=====

This article last reviewed: 28 September 1988

Under normal operation, the LaserWriter automatically purges downloaded fonts at the end of each print job. Fonts are retained in memory only when they have been manually downloaded.

(The number of downloadable fonts varies with the size of the font files, type of laser printer, and amount of available memory. When using the LaserWriter, four to six fonts may be downloaded per print job.)

If the fonts are not automatically purged at the end of the print job, they must be cleared from memory manually -- either by turning the printer off and on, or by resetting the printer, which forces a test page to be printed.

LaserWriter: How To Calculate The Cost Per Printed Page

Revised: 10/27/88
Security: Everyone

LaserWriter: How To Calculate The Cost Per Printed Page

=====

This article last reviewed: 28 September 1988

If you want to calculate the true cost-per-page for your LaserPrinter, or other printer, you should consider the following factors: cost of paper, cost of toner cartridges, electrical power consumption, depreciation, and labor costs.

However, for the simplest cost-per-page analysis, divide toner cartridge cost by the number of copies.

Example

$\$100.00 \text{ (toner cartridge)} / 4,000 \text{ (copies)} = \0.025 per copy

If the cost of paper is included in the calculation, the equation is: Cost of toner cartridge plus the cost of paper divided by the number of copies.

Example

$\$100.00 \text{ (toner cartridge)} + \$20.00 \text{ (paper)} / 4,000 \text{ (copies)} = \0.03 per copy

(NOTE: The number of copies printed per toner cartridge listed here (4,000) is an estimate and varies depending on the print density of the documents.)

AppleCD SC: Saving Song And Disk Titles With The CD Remote DA

=====

This article last reviewed: 29 September 1988

The CD Remote DA saves song and disk titles in the "CD Remote Programs" file in the System Folder.

The entry in the "CD Remote Programs" file is cross referenced against a CD ID number imbedded in the audio CD.

There are three resources in the "Programs" file: "IndX", "ProG", and "STR#":

- The "IndX" resource is the cross reference between the CD and the file.
- The "ProG" resource contains the sequence, if programmed, for playback of the tracks.
- The "STR#" resource contains the song and disk titles.

This cross-reference scheme allows you to type variations of the disk and song titles. The CD ID (IndX) is used to access the correct titles (STR#) and programmed sequence (ProG).

NOTE: You cannot save your entries while the audio CD is in play mode. If the audio CD is being played, the AppleCD SC does not have access to the CD ID imbedded in the disc. If a "Save" is performed during play mode, the titles are saved in the "Programs" file but not the CD ID.

Without the CD ID, the song and disk titles cannot be accessed. The CD ID is read after the Save button is clicked and before writing to the "CD Remote Programs" file.

For the proper associations to be saved, click the Save button during a period of no CD activity.

Apple Scanner: Four Must-Know Workarounds For Common Problems

Revised: 5/24/89
Security: Everyone

Apple Scanner: Four Must-Know Workarounds For Common Problems

=====

This article last reviewed: 5 October 1988

Here are four useful workarounds for common Apple Scanner problems:

17-Character File Name Limitation

This file name limitation applies to half-tone pattern names, as well as setting names (for example, Untitled Pattern 2). To work around, delete any setting names or half-tone pattern names that exceed the limit. Also, the system error occurs only when saving the file in PICT format.

Background Printing

Background printing of scanned images under MultiFinder may produce "streaks". This applies not only to AppleScan, but also to other applications that print scanned images. It is recommended that background printing be turned off whenever printing a document that contains scanned images.

Printing Scanned Half-Tones

In general, printed output of scanned half-tones looks best when the Graphics Smoothing, Faster Bitmap, and Precision Bitmap print options are turned off. Again, this applies to most applications. Use LaserWriter Driver 5.2, which is included on the AppleScan disk and the System 6.0 Printing Tools disk.

HyperScan

When starting HyperScan, a "Can't load Global variables" dialog may appear, preventing use of the stack. This occurs in extremely low memory situations on 1MB machines. Try turning off the RAM cache. If the problem persists, it may be caused by an INIT (or several INITs) using memory.

Using Apple Scanner With AppleFax Modem

Revised: 8/3/89
Security: Everyone

Using Apple Scanner With AppleFax Modem

=====

This article last reviewed: 5 October 1988

There are two ways to use the Apple Scanner and AppleFax Modem.

The first method scans into memory and sends the AppleFax from memory:

1. Place the document in the Apple Scanner.
2. Launch the AppleScan application.
3. In the AppleScan Resolution pop-up menu, select 200 dpi (Fax).
4. Press the Scan button.
5. Select the Chooser.
6. Select the AppleFax Resource icon from the Chooser.
7. Choose the AppleScan Page Setup command to set the page specifications. Click OK to confirm the command.
8. Choose the AppleScan Print command to set the Quality and Page Range options.
9. (optional) To change the station's phone number (the message that prints on the top of each page), the type of dialing, or the number of times the station redials a busy number, click the Setup button. When the changes are made, click OK to return to the Print dialog box.
10. Enter a phone number.
11. Click Send to send the file.

..TIL03332-Using_Apple_Scanner_With_AppleFax_Modem_(TA39151).pdf

The second method scans an image, saves it to disk, and sends the AppleFax from the disk:

1. Follow steps 1 through 8 of the first method.
2. Click the Save File button.
3. When the Save File dialog appears, click the Save button to save the file.
4. Quit the AppleScan application.
5. Launch the AppleFax application.
6. Drag an envelope from the New Envelope Stack to the Envelope View.
7. Drag an address-book entry to the envelope.
8. Double-click the envelope.
9. (optional) To look at an AppleFax file before adding it to the Envelope Contents directory, select the AppleFax file, and click Open.
10. Select the files that you want to add to the Envelope Contents directory.
11. Click the Add button to add the selected files.
12. Tell the station when to send the envelope.
13. Click OK to save changes.

LaserWriter IINTX: HD Fonts Are Accessible To IBM AT Compatibles

=====

This article last reviewed: 6 October 1988

If you have been using a LaserWriter Plus, your IBM PC/AT or clone can also access the fonts resident in the LaserWriter IINTX hard drive through the RS-232 interface.

The fonts installed on the LaserWriter IINTX hard disk will appear as if they were in the LaserWriter IINTX ROM. All fonts, whether in ROM or installed on the hard disk, should be fully accessible to any PC/AT or AT clone that can already access the fonts in a LaserWriter Plus.

Adobe and Apple designed the hard disk option so that LaserWriter IINTX operates transparently, and the user can thus access additional fonts without having to download them with utilities.

Interferon 1.0, 2.0: Problem Mistaking The LaserWriter For Virus

=====

This article last reviewed: 6 October 1988

Interferon 1.0 and 2.0, virus detection programs, report both LaserPrep 5.2 and LaserWriter 5.2 (from the 6.0 distribution) as "type 004 infections" -- that is:

"(004) 04/07/88 "SNEAK" Virus: Common System Folder files turned into INITs"

Interferon 1.0 and Interferon 2.0, like any other virus-detection tools, are not foolproof. They may suggest a virus where one does not exist, or not detect a virus that is present.

Interferon 3.0 does NOT report LaserWriter files as possible virus spreaders.

HyperCard 1.2.1: Supports Multilaunch Over AppleShare

=====

This article last reviewed: 11 October 1988

HyperCard 1.2.1 on an AppleShare File server is a multilaunch application -- provided HyperCard and its Home stack are in a folder with read-only access.

If HyperCard is launched by a user with read/write access, HyperCard cannot be run by another user. This has not changed with the new versions of AppleShare.

As long as a stack is locked, the stack can be accessed from a file server by more than one user. Neither HyperCard or the stacks are multiuser, and stacks cannot be written to by more than one user at a time.

LaserWriter: How To Eliminate Image "Ghosts" (7/95)

Article Created: 20 October 1988
Article Reviewed/Updated: 28 July 1995

TOPIC -----

When printing an image followed by a large black area on a LaserWriter, a "ghost" of the image sometime appears in the black area. This article describes a way to correct this ghosting effect on the Apple LaserWriter, LaserWriter Plus, or Laserwriter II printers.

DISCUSSION -----

The ghosting image anomaly is not unique to the Apple LaserWriter, LaserWriter Plus, or LaserWriter II printers; it is common to most laser printers and represents a problem with current laser-imaging technology. The ghosting may appear more pronounced with Apple equipment because many Apple applications use graphics AND text, rather than text only.

To work around the problem, print two or three copies of the document. When multiple copies of a page are printed, the organic coating on the imaging drum becomes more sensitive and is not as susceptible to the residual charges that cause ghosting.

LaserWriter IINTX: Cached Fonts Are Available To Host Computer

=====

This article last reviewed: 11 October 1988

Fonts cached on a hard disk connected to a LaserWriter IINTX are a local resource to the printer, and not the system creating the document.

When a specific font is requested, the LaserWriter checks its local resources for the desired font and loads the font information.

This process is contained within the architecture of the LaserWriter interrupter, and is transparent to the user. No additional software or commands from the sending system are required.

AppleWorks 2.1: Apple IIf Plus Disk Drive Labelling Correction

=====

This article last reviewed: 12 October 1988

The Apple IIf Plus has an internal 3.5" disk drive, which the older Apple IIf system didn't have. AppleWorks has a menu item under "Add Files" for changing current disk. When chosen, this menu item displays a list of available disks.

On an Apple IIf Plus with the internal 3.5" drive, AppleWorks 2.0 displays the following list of drives:

1. Built-in disk
2. Ext. disk IIf
3. Disk 3.5 #1
4. ProDOS directory

NOTE: AppleWorks 2.0 uses the following associations between slot/drive and the labels as displayed above:

- | | |
|---------------------|--|
| 1. Built-in disk | Slot 6, Drive 1 |
| 2. Ext. disk IIf | Slot 6, Drive 2 |
| 3. Disk 3.5 #1 | Slot 5, Drive 1 |
| 4. ProDOS directory | (the pathname typed in response to this selection) |

When running on a Apple IIf Plus:

1. The built-in disk is actually the first external 5.25" drive.
2. The "Ext. disk IIf" is the second external 5.25" drive.
3. The "Disk 3.5 #1" label is the internal 3.5" drive mounted in the Apple IIf Plus.

These labels are correct for the older Apple IIf systems, but the labels do not correctly identify the internal disk drive for the Apple IIf Plus. Claris has revised AppleWorks 2.0 to correct the associations. Contact Claris for information about the AppleWorks 2.1 update.

LaserWriter II P/C: Image Shifted On Page

Revised: 1/17/89
Security: Everyone

LaserWriter II P/C: Image Shifted On Page

=====

This article last reviewed: 31 October 1988

BEFORE YOU START: Familiarize yourself with the LaserWriter II Technical Procedures. Be sure to follow proper ESD procedures.

Problem Description:

The image printed on the Laserwriter II is shifted or not placed properly on the page.

Background Information:

There are three switches (SW201, SW202, SW203) which detect which size paper cassette has been installed in the printer. If these switches become bent, or are triggered incorrectly the image will shift on the page depending on the cassette size the printer thinks is inserted. The image will be shifted down and to the right on the paper. The amount of shift depends upon which cassette the printer detects. For example, if the printer thinks it detects an A5 cassette then the image will be shifted down about 1/2" and to the right about 1/4". The built in print engine test is aligned perfectly on the page.

Cure:

- #1: Straighten the microswitch arms or replace the entire microswitch assembly.
- #2: Check the paper cassette for damage.

If this does not solve the problem refer to the LaserWriter II Technical Procedures for further information.

A/UX: An Example Setup Of UNIX Mail For The Macintosh (9/94)

Revised: 9/13/94
Security: Everyone

A/UX: An Example Setup Of UNIX Mail For The Macintosh (9/94)

=====

Article Created: 21 October 1988
Article Reviewed/Updated: 13 September 1994

TOPIC -----

This article describes a shareware electronic mail development project for UNIX at the University of Minnesota. The idea was to create a simple system that would insulate users from having to learn UNIX or VMS. (Most campus administrators and secretaries at the university fall into this category.)

DISCUSSION -----

Because they were already running the CAP AppleShare file server software on a Sun workstation, they decided to take mail from the UNIX mailer and deposit it in an AppleShare volume. This means the user's mail is put onto an AppleShare disk and is readable by their favorite word processing application. Electronic mail appears as a normal Macintosh document. One configuration has the system set up so that incoming mail appears as Microsoft Word documents.

Conversely, they set up a folder on the AppleShare volume where any file dragged into the folder is submitted to the UNIX mailer. To be treated as mail, the file needs to obey two conventions:

- The first line of the file is the name and address of the receiver.
- The second line of the file is the subject.

A 20-line, C-shell program puts incoming mail into the appropriate AppleShare volume and mails outgoing mail from the outgoing mail folder. This process gave them two-thirds of a standard electronic mail system: sending and receiving mail.

The other third of the system is notification when mail arrives. To cover this requirement, they wrote a tiny (40K) application called "Nag." Nag runs under MultiFinder and periodically looks into a folder to see if any new files arrived. If new files appear in the folder, Nag uses the Macintosh notification manager to alert the user. If you want to know when mail arrives you can run

Nag. (Nag is small enough to run it and a word processing application under MultiFinder -- even on a 1MB Macintosh.)

The whole project is called "piece mail," because it is a mail system built from small pieces:

- AppleShare Server software
- A UNIX machine
- A shell script to move mail into the AppleShare Server volume
- The Nag program to notify users when new mail has arrived
- A word processing application to read and edit mail messages.

Although the school is using CAP AppleShare software on a Sun workstation, running UNIX, this same technique also should work for VMS VAXes with Alisa or Pacer AppleShare Server software. All this substitutes for SMTP mail services on the Macintosh.

GS/OS: Polling Drives For Disks Is Necessary

=====

This article last reviewed: 21 October 1988

Some users have expressed concern that the Apple IIGS GS/OS polls disk drives for the presence of a disk. The polling of drives under GS/OS is normal. Unlike the Macintosh, which has built-in hardware and firmware to detect a disk, the Apple IIGS does not. The Apple IIGS, via GS/OS, needs to poll the drives to determine whether a disk has been inserted. There is no way to disable the drive polling.

EtherTalk: Thin-Wire Cabling Strategy

Revised: 12/3/88
Security: Everyone

EtherTalk: Thin-Wire Cabling Strategy

=====

This article last reviewed: 1 November 1988

This article discusses a wiring strategy for thin-wire Ethernet cabling (RG58U cable) and the Macintosh II EtherTalk card.

Basically, RG58U cable must always loop through the wall plate (via a BNC connector). If no computer is present, pass the cable out through one hole in the plate and then back in through the other hole (the pass-through loop strategy).

If a computer is present, run the cable out to a T-connector mounted directly on the back of the computer and connect it to the T-connector. (Important: Xerox says that the T-connector MUST be within 1/2 inch of the card.) Run the continuing cable from the other side of the T-connector back through the second hole in the wall plate.

Macintosh: Third-Party Serial-to-Parallel Solution

=====
Article Created: 1 November 1988
Article Last Reviewed: 9 June 1992
Article Last Updated: 9 June 1992

TOPIC -----

Is there any way to connect a parallel printer to the serial port of my Macintosh?

DISCUSSION -----

There are two solutions, both from Orange Micro:

The Grappler 9-pin (formerly called Grappler C/Macintosh/IIGS) provides a parallel interface system. The Grappler device plugs into the serial port on the Macintosh. It does a serial-to-parallel conversion using the ImageWriter II driver. It works with Epson, Okidata, Panasonic, and other Epson-compatible printers. (A special adapter cable from Orange Micro is required for both versions of the Macintosh 512K.)

The Grappler LX (formerly called Grappler LQ) is similar and does the serial-to-parallel conversation for third-party printers with 24-pin printheads. The device lets Hewlett-Packard-compatible laser printers, the HP DeskJet, and Epson or Toshiba 24-pin dot matrix printers, to work like the ImageWriter LQ printer. It does not work with the Macintosh 512K and Macintosh 512Ke.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Macintosh: How To Use AFE To Import ProDOS PFS File Data

Revised: 12/5/88
Security: Everyone

Macintosh: How To Use AFE To Import ProDOS PFS File Data

=====

This article last reviewed: 21 October 1988

A good way to move data from the ProDOS version of PFS File to a Macintosh is to follow three steps:

- 1) Issue the PFS File "Copy Forms" command (explained in Chapter 9 of the PFS File manual) to print the file to disk as a ProDOS "delimited text" file.
- 2) Read this ProDOS text file into AppleWorks.
- 3) Print the file to disk to create a text file that he can import into the Macintosh. The resulting file is a true "TXT"-type file.

Some people want to use the PFS File "Copy Forms" command (explained in Chapter 9 of the PFS File manual) in a one-step operation. The problem with this is that Copy Forms does not create TXT-type file, but rather a "delimited text" file. Apple File Exchange does not see such a file as a text file and translates it as "default" mode. The additional step (moving the file into and out of AppleWorks) changes the file to a true TXT-type file that AFE can accomodate.

Apple File Exchange accomplishes file translation using scripts. You can write a script that accommodates the file type that has been assigned to the PFS File. To implement the translator, programming in the AFE environment is required (see "Apple File Exchange Technical Reference Package v1.1", available from APDA).

Software Publishing Corporation, publishers of the PFS series, recommends that the customer print the document to a disk. This assigns a TXT type to the printed document. However, this method writes the file in the screen layout format or a mailing label layout format. It does not automatically separate the fields or the records as the method described here does. For more information, search on "Software Publishing Corporation".

You can also change the file type with a file editor. However, this method is

more technical and riskier than using the AppleWorks method.

ImageWriter LQ: Available OCR Fonts

Revised: 12/5/88
Security: Everyone

ImageWriter LQ: Available OCR Fonts

=====

This article last reviewed: 1 November 1988

As of this article writing, no OCR-A or OCR-B fonts designed as 3x fonts for the ImageWriter LQ are available. However, you can generate 3x fonts from an existing screen font using a font editor like Altsys FONTastic Plus.

For example, a 12-point font printed on the ImageWriter LQ needs a 36-point font installed in the System. OCR-A is available in 12-point, but not in 36-point. To create a 36-point font, open the 12-point font in FONTastic Plus and have FONTastic Plus generate it. Save that 36-point font, and install the generated font into the System file. Some cleanup of the generated font may be required within FONTastic Plus on a Fat Bits style screen.

Also, NeoScribe International creates custom fonts. They also sell a PostScript OCR-A font with the screen font.

For more information, search on the above company names.

A/UX: Bourne Shell Metacharacters (6/93)

Article Created: 21 October 1988
Article Reviewed/Updated: 24 June 1993

TOPIC -----

This article discusses Bourne shell metacharacters.

DISCUSSION -----

A metacharacter is a character that performs a special function in the shell, like expanding a file name or redirecting output. In fact, the metacharacters in this article fall into two categories: wildcard characters for file name expansion and redirection of input/output and process.

File name expansion characters include

- Asterisk *
- Brackets []
- Brackets-Hyphen [-]
- Question mark ?

Input/output and process redirection characters include

- Ampersand &
- Back quote `
- Backslash \
- Braces { }
- Double greater than > >
- Greater than >
- Less than <
- Parentheses ()
- Semicolon ;
- Slash /
- Vertical bar |

The article is divided into two sections (one for each type of character). All metacharacters are listed alphabetically within their sections.

FILE NAME EXPANSION METACHARACTERS

The Asterisk

The asterisk (*) substitutes in a file or directory name for zero or more characters, except a leading period (like ".ash").

Example: The command

```
ls *ash
```

returns file names ending with the letters "ash" like "ash", "bash", "cash", "mash", and "splash". However, it won't return strings that have characters after the "ash" like "bash.tmp" or "bashful".

Brackets

Brackets ([]) cause the shell to look for a match for each character between the brackets, one at a time. It does not match the period character.

Example: `ls [bm]ash` returns file names "bash" and "mash", but not "cash" or "bash.tmp".

A variation is brackets with a hyphen separating two characters. It causes the shell to match any character within the range of these characters in a file or directory name.

Example: `ls [a-c]ash` returns file names that have letters in the range from "a" through "c" as the first character of their name and that are followed by the letters "ash". Thus, "ash", "bash", and "cash" match, but not "dash" or "mash".

You can place a bracket metasequence anywhere in a string.

Question Mark

The question mark (?) substitutes for any ONE character in the same position in a file or directory name. The question mark does not expand file names, nor does not match a leading period.

Example: `ls ?ash` returns only file names that have one character followed by the characters "ash". Thus, "bash", and "cash" match, but not "ash" or "splash".

REDIRECTION METACHARACTERS

Ampersand

The ampersand (&), placed at the end of a line, causes the task it follows to run in the background. When using the ampersand, the shell returns the task's PID (Process ID Number). Note: In the Bourne shell, you cannot retrieve a task from the background.

Example: `cat /etc/passwd &`

Back Quotes

The back quotes (` `) contain any UNIX command. When the shell executes the line containing the back-quoted command, it replaces the command and with the command's output in the string. Without the back quotes, the shell would treat a command like an ordinary string.

For example,

```
echo today is date
```

returns "echo today is date", whereas

```
echo today is `date`
```

returns "today is " followed by the system date.

Backslash

The backslash (\), preceding a metacharacter, causes the shell to interpret the character as a regular character rather than as a metacharacter. Typically, this can stop a variable from returning its value.

For example, type in the following three lines of code. And notice that the third line does not return the variable's value.

```
x=hi
echo $x
echo \$x
```

Dollar Sign

The dollar sign (\$) causes the shell to evaluate or display the value of the variable the dollar sign precedes. The following three lines output "hi", the contents of variable x.

```
x=hi
echo $x
```

Double Quotes

The double quotes (" ") serve three purposes. First, it lets you put tabs and spaces in a string as you assign the string to a variable. Second, when you display the contents of a variable, surrounding the variable name in double quotes preserves tabs and multiple contiguous spaces and tabs.

Try this example:

```
y=me and you
```

The shell refuses the command when it hits the first space. Try this (including multiple spaces after "and"):

```
y="me and    you"
echo $y
echo "$y"
```

The third purpose for double quotes is that they can "seal in" command characters, so that these characters appear as literals. For example, typing

```
echo today's
```

causes the system to display a greater than sign. It's waiting for further input, input that must conclude with a single quote. The command

```
echo "today's"
```

just prints the word.

Greater Than and Double-Greater-Than

Both these commands take data from a source command and send that data to the target file as if it were standard output. If the file doesn't exist the command creates one. The difference is that greater-than always *writes* to the target file, thus erasing any data already in the file. The double-greater-than character always *appends* the data to the file.

To see these characters at work, try this command-line sequence:

First, check to see if you have a file named "doc." If you do, use a different file name.

```
ls doc
date > doc
cat doc
who am i >> doc
cat doc
cal 11 1993 > doc
cat doc
```

Less Than

The less than (<) causes a file to be treated as a standard input for the command. The example writes the file names in the current directory into doc, It then hands the contents of doc to the sort command for a reverse sort to the screen

```
ls < doc
```

```
sort -r < doc
```

Parentheses

The parentheses -- () -- group several commands for execution in a subshell with command output passed as standard input to the next command on a pipeline. Notice the difference when you use parentheses and when you don't in this example:

```
date; who am i > doc
cat doc
(date; who am i) > doc
cat doc
```

Without parentheses, the shell executes the date command without sending its output to doc. The shell pipes the who am i output, because it is immediately adjacent to the greater than.

Semicolon

The semicolon (;) causes commands on the current line to be executed sequentially. Note the example for parentheses and the example below:

```
date ; ls
```

Single Quotes

Put single quotes (') around special characters when you do not want the shell to interpret them.

Note: if a back quote occurs within the command, it must be escaped with a "\" (backslash). Otherwise, the usual quoting conventions apply within the command.

Vertical Bar

The vertical bar (|) causes the standard output for the first command and to be treated as the standard input for the second command. That is, the vertical bar combines commands into a pipeline, passing data from one command to another without an intervening file. The example passes the listing for the current directory directly to the sort command for a reverse sort printed to the screen:

```
ls | sort -r
```

MacWorkStation-to-AS400 ASCII Protocol

Revised: 12/5/88
Security: Everyone

MacWorkStation-to-AS400 ASCII Protocol

=====

This article last reviewed: 1 November 1988

There are two hardware devices that provide IBM ASCII protocol for the AS400 Async Controller.

- Protocol Convertor Model 5208
- ASCII Workstation Controller 9404

Apple has tested both in VT100 mode. Generally, VT100 is an Xon/Xoff handshaking device, although it can use hardware handshaking.

Using the asynchronous protocol provided with MacWorkStation, MacWorkStation codes travel from Macintosh across either IBM's 5208 or 9404 to the AS400. The host application on the AS400 needs to accept and transmit the appropriate MacWorkStation codes to complete the environment.

GS/OS: How To Install Drivers And Other Devices

=====

This article last reviewed: 1 November 1988

The SYSTEM.DISK (included with Apple IIGS System Disk 4.0 -- GS/OS), does not contain the drivers for a 5.25-inch or SCSI drive. Without these drivers installed, the system cannot access the 5.25-inch or SCSI drive.

To install these (and other) drivers:

1. Create a start-up disk and make a back-up copy.

IMPORTANT: Do not run the Installer program on your original start-up disk.
Also, do not install GS/OS on a third-party application disk.
The application may work only with the original System files.

2. Run the Installer program (on the SYSTEM.TOOLS disk) so that it installs drivers on the back-up copy of the start-up disk.
3. Select "Apple Disk 5.25" for the 5.25-inch drive.
4. Select "SCSI Hard Disk" for the SCSI drive.

Contact the developer before upgrading to GS/OS, if you have any compatibility questions.

The following can be added with the Installer program:

Additional Fonts
Advanced Disk Utility
Apple Disk 5.25
Apple MIDI
AppleTalk ImageWriter
AppleTalk ImageWriter LQ
Card 6850 MIDI
CD-ROM
Direct Connect ImageWriter

Direct Connect ImageWriter II
Epson Printer

Apple IIGS: GS/OS Support For Epson Printers

=====

This article last reviewed: 23 November 1988

Apple IIGS System Disk 4.0 and GS/OS support printing to these Epson printers through the Practical Peripherals Graphic Card:

FX-100
FX-850
FX-1050
LQ-850
LQ-1050
LX-800
RX-80

To use these Epson printers, you must have installed the Practical Peripherals Graphic Card; it is the only interface card supported. Also, all eight switches on the printer must be in the UP position. Use either the printer default setting or see the Practical Peripherals Graphic Card manual for individual printer settings.

For more information, search in the Tech Info Library under "Practical Peripherals" and "Epson."

Macintosh II: Automatix Offers Industrial-Grade Model

=====

Article Created: 23 November 1988
Article Last Reviewed: 29 June 1992
Article Last Updated:

TOPIC -----

I need to use a Macintosh II in a very harsh environment, ie. factory.
How can I protect my Macintosh?

DISCUSSION -----

If you need an industrial-grade Macintosh II, look into Automatix's modified Macintosh II. The AI-90 computer integrates Macintosh II innards with a steel case (rated NEMA 2), a shock-mounted hard disk, and temperature- and power-monitoring circuits.

A second computer, the AV-90, extends the AI-90 for video digitization. It includes a frame-grabber card and an interpreted language for imaging and I/O work -- MacRail.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Apple IIe: Input Devices For Disabled Individuals

=====

This article last reviewed: 23 November 1988

This article lists companies who make software and hardware that enable the disabled to use Apple computers.

Contact the Trace Research & Development Center at the University of Wisconsin concerning their software registry and listing of literature and programs.

Both Zygo Industries and Prentke Romich, have switches and devices to aid input to the computer. Zygo also makes various software packages that can do abbreviation expansion, and math figures. A demo disk product shows input and output techniques for the disabled.

Using one of these products with the Adaptive Firmware Card from Don Johnston Development Company allows users to enter information into most computer programs. The card allows 16 different input methods, including single-switch scan, Morse Code for two switch users, expanded keyboard, and so on. This card can be installed by a nontechnical person and does not disrupt use of the computer by able-bodied individuals.

AppleCD SC: How To Use The High Sierra Format With AppleShare

=====

This article last reviewed: 11 November 1988

You can install software on an AppleCD SC drive, so that High Sierra CDs can be shared from an AppleShare file server. To do this, you need a CD Setup disk (with version v2.0.1 or greater of AppleCD SC). This disk contains drivers that support the High Sierra CD-ROM format. To install, follow these steps:

1. Run the Installer program on the CD Setup v2.0.1 disk.
2. Choose the "AppleCD SC (v2.0.1)" script.
3. Select the AppleShare server start-up volume.
4. Click "Install."

After the High Sierra drivers have been installed, follow the directions in the AppleShare File Server Administrator's Guide (Copyright 1987,1988 by Apple Computer, Inc; part number 030-1343 or 030-1023 with Tell Apple card) for using CD-ROM drives.

LANStar/EtherTalk: Macintosh II Bridge Not Available

=====

This article last reviewed: 11 November 1988

A LANStar card and an EtherTalk card can be placed into a Macintosh II. However, this does not bridge the two networks through the Macintosh II. It merely lets the two networks have branches to the same machine, but there is no communication between the networks or between machines on the different networks.

Software written specifically to recognize both cards (and networks) also is required. This software needs to implement functions similar to those provided by a Kinetics FastPath for LocalTalk and Ethernet. Currently, there is no software that we know of that can do this. Northern Telecom software provides bridging functions between LocalTalk and LANStar, but it does not do the same with the EtherTalk card.

Access II: Does Not Support VT100 Line Graphics

=====

This article last reviewed: 21 September 1988

Apple's Access II does NOT support the VT100 line graphics character set. If you need this character set, there may be third-party terminal emulators for the Apple II family that provide VT100 character graphics.

Apple is not currently aware of manufacturers of such emulators. If you have information on third party suppliers, please contact the Apple Technical Information Library (at AppleLink address TECH.DB).

High-Density Disks: Don't Format them in 400K/800K Drives

=====

Article Created: 5 December 1988
Article Last Reviewed: 22 August 1991
Article Last Updated: 22 August 1991

TOPIC -----

This article explains why a high-density disk should not be formatted in 400K or 800K drives.

DISCUSSION -----

If a high-density disk is formatted in a normal 800K or 400K drive, it functions as an 800K or 400K disk; however, when such a disk is used in the Apple SuperDrive (formerly Apple FDHD), a dialog box appears stating that the disk was improperly formatted.

SuperDrive disks have a special notch which allows the SuperDrive to recognize the media as high density (1.4MB). Standard 800K and 400K drives CANNOT detect the notch, and will format a high-density disk as a regular 800K or 400K disk.

High-density media should NOT be formatted in a 800K or 400K drive.

High-density disks are physically different from double-density disks and are tested to a different specification. The coating on high-density disks is thinner and has finer particles. These disks require a less intense magnetic field from the read/write head to properly align the magnetic particles within the data cell during a write cycle.

The magnetic field generated by Apple 800K and 400K drives is too strong and may cause data loss.

Thus, the SuperDrive, in conjunction with the system software, recognizes that the high-density disk was formatted improperly and gives the user the option to re-format it or eject it.

AppleTalk: Updated Name-Binding Protocol (NBP) List

=====

This article last reviewed: 06 October 1989

Here is a list AppleTalk NBP Types. (NBP means "name-binding protocol" -- an AppleTalk protocol that allows users to assign familiar character string names to network devices.)

NBP Type	Description
-----	-----
AFPServer	Apple Filing Protocol compliant file server
Apple IIe Boot	AppleShare, with Apple IIe boot support
Apple IIGS	AppleShare, with Apple IIGS boot support
Apple IIe	Apple AppleTalk Card
Apple IIGS	Apple AppleTalk GS
APS Spooler	Alisa Systems VAX-spooled LaserWriter
ASManager	AlisaShare Network Manager
ATK/VMS Bridge	AppleTalk for VMS bridge
C-Server	Solana, 3 serial ports
ChooserName	Farallon RegisterName node
DECNet Gateway	Alisa Systems DECNet gateway
GatorBox	Cayman GatorBox, AppleTalk-Ethernet
I-Server	Solana, AppleTalk-AppleTalk
ImageWriter II	AppleTalk ImageWriter II
InBox Mailserver	InBox Mail server node
InterBridge	Hayes, AppleTalk-AppleTalk (NOTE: Space is last character of the NBP type.)
IPADDRESS	NCSA Telnet (MacIP) terminal
LaserShared	Apple LaserShare-spooled LaserWriter
LaserWriter	LaserWriter or Spooler process
Liaison	Infosphere Liaison Software Bridge
LQ	AppleTalk ImageWriter LQ
Macintosh II	Apple Responder node
Macintosh Plus	Apple Responder node
Macintosh SE	Apple Responder node
MS-DOS 3.3	Apple LocalTalk Card

Multitalk	Abaton, 3 serial ports(Discontinued Product)
MWSHost	MacWorkStation Host
NetBridge	Shiva, AppleTalk-Async
NetModem	Shiva, AppleTalk modem
NetSerial	Shiva, 1 serial port
NMClient	Shiva NetModem client
no NBP	Northern Telecom, LANSTAR-AppleTalk
no NBP	Northern Telecom, PrintWay
no NBP	Northern Telecom virtual LANSTAR bridge
no NBP	Kinetics FastPath, AppleTalk-Ethernet
Node	LaCie SilverServer node
NSClient	Shiva NetSerial client
Odesta Double Helix	Helix Data Base Server
Odesta MultiUser Helix	Helix Data Base Server
OmnisAT	Omnis Multiuser database user
pcLINK	Pacer, virtual AppleTalk bridge
ProDOS 16 Image	AppleShare, with Apple IIGS boot support
QMServer	CE Software QuickMail server
QMSNtest	CE Quick Mail B5 node
QuickMail	CE Quick Mail B5 client node
R-Server	Solana, AppleTalk-Async
ResourceServer	Microsoft Mail server
ResourceTester	Pacer Microsoft Mail server
S-Server	Solana, 1 serial port
SerialX	LaCie SilverServer node
Spooler	AppleShare Print Services Spooler
TFTPServer	Cayman TFTP Server
Timbuktu Host	WOS Timbuktu host node
Timbuktu Serial	WOS Timbuktu node
Top2Serial	TOPS node
Top2Server	TOPS server node
Top2Station	TOPS client node
UnixMailListener	Star Nine UNIX Mail server

Macintosh: SCSI Bus Does Not Use True DMA Mode

=====

This article last reviewed: 25 October 1988

The Macintosh family of computers does not support true DMA transfers via the SCSI chip.

The SCSI chip can operate in two modes: normal mode and pseudo-DMA mode.

- In normal mode, the SCSI driver software manages the handshaking to communicate with a peripheral SCSI device.
- In pseudo-DMA mode, the SCSI chip's internal logic handles all the SCSI bus handshake signals automatically.

(NOTE: For more information on the SCSI chip and DMA, see pages 5-24, 12-25, and 20-21 of the "Macintosh Family Hardware Reference" manual from Addison Wesley, (ISBN# 0-201-19255-1).

Ethernet, LocalTalk: Number Assignments Don't Affect Performance

=====

This article last reviewed: 1 November 1988

When creating an Ethernet and LocalTalk network, performance is not effected if the assigned network numbers are both high and low (for instance: 1,2 or 820,821)

It makes no difference what number is assigned since the field size remains constant. If a small number is used and the field is not "filled", zeros are transmitted as place holders.

Apple IIC Plus: External Drive Configurations

=====

This article last reviewed: 8 November 1988

The following table shows all possible drive configurations for the Apple IIC Plus computer:

Drive 1	Drive 2	Drive 3	Count (internal included)
-----	-----	-----	-----
Apple 3.5"	Apple 3.5"	UniDisk 3.5"	(4-3.5")
Apple 3.5"	UniDisk 3.5"	UniDisk 3.5"	(4-3.5")
UniDisk 3.5"	UniDisk 3.5"	UniDisk 3.5"	(4-3.5")
Apple 3.5"	Apple 3.5"	Apple 5.25"	(3-3.5" 1-5.25")
Apple 3.5"	UniDisk 3.5"	Apple 5.25"	(3-3.5" 1-5.25")
UniDisk 3.5"	UniDisk 3.5"	Apple 5.25"	(3-3.5" 1-5.25")
Apple 3.5"	Apple 5.25"	Apple 5.25"	(2-3.5" 2-5.25")
UniDisk 3.5"	Apple 5.25"	Apple 5.25"	(2-3.5" 2-5.25")
Apple 3.5"	Apple 3.5"	none	(3-3.5")
Apple 3.5"	UniDisk 3.5"	none	(3-3.5")
UniDisk 3.5"	UniDisk 3.5"	none	(3-3.5")
Apple 3.5"	Apple 5.25"	none	(2-3.5" 1-5.25")
UniDisk 3.5"	Apple 5.25"	none	(2-3.5" 1-5.25")

Apple 5.25"	Apple 5.25"	none	(1-3.5" 2-5.25")
Apple 3.5"	none	none	(2-3.5")
UniDisk 3.5"	none	none	(2-3.5")
Apple 5.25"	none	none	(1-3.5" 1-5.25")

Slot and Drive Configurations

Internal 3.5" slot 5 drive 1 (PR#5 boots this drive)

First external 3.5" slot 5 drive 2 *

Second external 3.5" slot 2 drive 1

Third external 3.5" slot 2 drive 2

First external 5.25" slot 6 drive 1 (PR#6 boots this drive)

Second external 5.25" slot 6 drive 2

* The first external 3.5" boots at power on or reset if no disk is inserted in the internal drive. This disk does not boot when a PR#5 is entered.

- The Apple 3.5" is an 800K platinum drive.

- The UniDisk 3.5" is an 800K white drive.

- The Apple 5.25" is a 140K platinum drive (formerly called UniDisk in the beige color).

Macintosh: Logic Boards And VDE Approval

Revised: 12/5/88
Security: Everyone

Macintosh: Logic Boards And VDE Approval

=====

This article last reviewed: 8 November 1988

There are no differences between the domestic and international Macintosh logic boards that would limit VDE approval (VDE, or VDE 0871, is a German code governing electronic components and performance).

However, the logic boards produced for domestic Macintosh systems are tested to meet DOMESTIC certification requirements only. Even though the logic boards are the same, the components used will be sourced from different vendors, depending on where the boards are produced.

This picture may be further complicated because some countries require vendor source information for certification. If the vendor source is changed, a new certification is required.

Apple IIGS: GS/OS 4.0 Incompatible With AppleShare (3/93)

Revised: 3/25/93
Security: Everyone

Apple IIGS: GS/OS 4.0 Incompatible With AppleShare (3/93)

=====

Article Created: 5 December 1988

Article Change History

03/25/93 - REVISED

- To add version number 4.0 because later versions of GS/OS are compatible with AppleShare.

TOPIC -----

Apple IIGS system software, GS/OS 4.0, part of Apple IIGS System Software 4.0, is designed for the stand-alone user.

DISCUSSION -----

GS/OS 4.0 DOESN'T support the AppleShare File Server; however, GS/OS 4.0 CAN use an AppleTalk printer.

The AppleShare IIGS Workstation Software provides ProDOS 16 from System Disk 3.2, which allows Apple IIGS access to the AppleShare File Server.

Later versions of GS/OS ARE compatible with AppleShare. Apple highly recommends upgrading to GS/OS 5.0.4 or later.

Apple IIGS: How To Print Low-Res/High-Res Graphics Files

=====

Article Created: 5 December 1988

Article Change History

1/19/93 - UPDATED
• Beagle Brothers now WordPerfect Corporation.
11/9/88 - REVIEWED
• For accuracy.

A low-resolution graphics file on the Apple IIGS can be printed from BASIC without using any special interface cards (for instance, an Apple IIGS with an ImageWriter II connected to the serial port) using Triple-Dump from Beagle Brothers (now WordPerfect Corporation).

This application lets any Apple II prints not only low-resolution, but high-resolution, double-high-resolution, and double-low-resolution files, as well as 40-column and 80-column text. Triple-Dump routines can also be used as part of BASIC programs.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Macintosh: Interferon and "Sneak" Virus

=====

This article last reviewed: 9 November 1988

Some users have asked about a "Sneak" virus, which supposedly turns commonly used System Folder files into "INIT" files and places an "INIT" resource into these files.

There is also some confusion about the misidentifications frequently made by the anti-virus program "Interferon".

Interferon 2.0 is likely to report that the files "LaserWriter" and "Laser Prep" are infected. Interferon 3.0 frequently reports that the "Finder" and "DAHandler" files are infected -- even when they are not.

Apple is not aware of a particular virus called "Sneak". (The word "Sneak" is generally used to describe a TYPE of virus, not a specific virus.)

Macintosh PrintMonitor: Error -1096 Is An AppleTalk ATP Error

=====

Article Created: 5 December 1988
Article Last Reviewed: 6 November 1991
Article Last Updated: 5 December 1988

TOPIC -----

This article describes the -1096 error that may come up when using PrintMonitor.

DISCUSSION -----

If you have been getting the -1096 error when printing under the PrintMonitor, it probably has something to do with your AppleTalk network setup.

Error -1096 is an AppleTalk ATP error that indicates the ATP sendRequest has failed because the retry count has been exceeded. This means that the workstation doing the printing is having a difficult time communicating with the LaserWriter or Print Server.

This suggests some type of AppleTalk network problem, which may be either physical or logical. Check the network for loose connections and proper topology. Also, AppleTalk traffic may be preventing the proper communication between the two devices.

AppleShare: Use Same Version On Server And Workstations

=====

This article last reviewed: 10 November 1988

If you are running AppleShare 1.1 under System 4.2 and Finder 6.0 on Macintosh Pluses and Macintosh SEs, and experiencing a problem with file creation dates, it is probably a versions-compatibility problem.

One example would be: looking at a directory on the server from any node, all the file creation dates show the year as 2028. The same files, when viewed from the server, are marked 1988. When a file is modified from a node and viewed on the server, the date modified is 1948.

Such an anomaly is usually noticed when the server is using a different version of AppleShare software than the workstations.

If the server is using v1.1, make sure that the workstations are using v1.1, or both the server and workstations can be upgraded to v2.0.

ImageWriter LQ: How Rated Speed Is Determined

=====

This article last reviewed: 10 November 1988

Here are the exact conditions under which the printer speed specifications of the ImageWriter LQ were measured, including hardware, software, and fonts used.

Hardware: Macintosh
Software: BASIC
Font: 10 cpi, in Draft fixed-pitch mode for the "draft" rating
Text: Shannon text consisting of characters and spaces

The "rated speed" refers to the printer speed at full carriage speed, excluding ramp time to accelerate and decelerate the carriage.

A program was written in BASIC and run on the Macintosh to print standard Shannon text (a combination of letters and spaces that approximates English), which all printer companies use to measure speed. This was done to minimize the Macintosh's processing time and the data transmission time.

The data sheet has additional speed ratings for the NLQ and LQ modes.

NOTE: Throughput ratings for the ImageWriter LQ are lower than speed ratings. Throughput ratings include ramp time, line feed time, etc. (For example, the throughput rating for the ImageWriter LQ in Draft mode is 155 cpi.)

Macintosh II: DIP- And Surface-Mounted SIMMs Are Equivalent

=====

Article Created: 10 November 1988
Article Last Reviewed: 21 July 1992
Article Last Updated:

TOPIC -----

Can both DIP-mounted and surface-mounted SIMMs be used together in a Macintosh II with HD40 SC and 4MB RAM? Are all Macintosh II computers with HD40 SC and 4MB RAM supplied with DIP-mounted SIMMs?

DISCUSSION -----

There is no problem mixing DIP-mounted and regular surface-mounted SIMMs in the same computer. To the computer, they are the same. Macintosh II computers with HD40 SC and 4MB RAM may be supplied with either DIP-mounted SIMMs or surface-mount SIMMs.

Apple HD-20: How To Convert It Into A SCSI Device

=====

This article last reviewed: 10 November 1988

There is a product that converts an Apple HD-20 into an SCSI device. Available from Personal Computer Peripherals Corporation, it is called HD-20 WSI.

The HD-20 WSI is an upgrade for the original Macintosh HD-20 that allows it to interface with the Macintosh Plus, Macintosh SE, and Macintosh II via the SCSI port. The HD-20 WSI modification provides users with significantly faster access to the data stored on the hard disk.

The modification consists of a plug-in circuit board, interface cable, and utility software. The circuit board uses the existing HD-20 connectors and requires no soldering. The utility software includes HFS Backup, Eureka (a file finding application), a floppy disk copy program, and ImageWriter/LaserWriter spoolers.

Macintosh II: Using Full SuperMac Screen With AppleScan Software

=====

Article Created: 10 November 1988
Article Last Reviewed: 1 July 1992
Article Last Updated:

TOPIC -----

I have a Macintosh II with two monitors, the AppleColor High Resolution RGB Monitor (13") and a SuperMac 19" monitor with a SuperMac video card. I notice that when I use the Apple Scanner, the AppleScan software seems to limit the size of the window to the size of the Apple 13" monitor. In other words, the document window cannot be resized to the full size of the SuperMac display.

DISCUSSION -----

When the AppleScan software is launched, it calculates the dimensions of the main screen (the screen with the menu bar) in pixels. The AppleScan software assumes that no screen is larger than the main screen, and so does not allow a window to be resized larger than the main screen as would be normal.

However, by holding down the COMMAND key while resizing the window, the window can be resized to fill the SuperMac display.

(NOTE: This technique may work with other applications; however, it may cause problems if the window is resized larger than the software can support.)

Macintosh IIX: ROM SIMM Size And Position

=====

Article Created: 16 November 1988
Article Last Reviewed: 20 July 1992
Article Last Updated:

TOPIC -----

Where is the ROM SIMM in the Macintosh IIX located? And how large is it?

DISCUSSION -----

The new ROM SIMM in the Macintosh IIX is located 1/2 inch to the left of the RAM SIMMs when looking at the machine from the front. The ROM SIMM is about 3/8" taller than DIP-mounted SIMMs.

Because of its height, the new ROM SIMM may cause problems with the installation of third-party, large capacity, full-height disk drives.

If DIP-mounted SIMMs currently cause installation problems with the drives in question, then the ROM SIMM will make this problem more pronounced.

LaserWriter II: Scanner Cable Problem/Cure

=====

This article last reviewed: 1 December 1988

Symptom:

When the I/O PCB is connected, the Scanner spins extremely fast when power is turned on.

Background Information:

Occasionally the Scanner will spin very fast, even if the I/O board is not connected. Usually when this happens the DC Controller board or the Scanner assembly is defective. In this particular case, when the I/O board is installed and the shield connects to ground, the Scanner spins very fast.

Cure:

To confirm this problem, pull out the I/O PCB and Power On. If it runs normally, turn the printer off, install a plug on J209 of the DC Controller board or use a clip and connect the 2 pins of J209 together (J209 connects signal ground to frame ground); then turn the printer on. If the Scanner spins very fast then replace Scanner harness cable.

LaserWriter II: Black Printout Problem Cure

=====

This article last reviewed: 5 January 1989

Problem: The printout from the LaserWriter II is black except for the top which may consist of 5 thin white lines 1 to 1.5 inches apart. There is also excess toner spilled around the corona wire assembly. This may occur after the corona assembly or the transfer guide assembly has been removed and replaced.

Cure: There is a brass colored grounding tab on one side of the transfer guide assembly, (if you are facing the printer from the paper tray end it's on the left side of the corona assembly) that should be in contact with the grounding spring on that side of the corona assembly. The tab pivots and can be in the wrong position when the corona assembly or transfer guide is removed and reinstalled.

GS/OS: How To Use It With A ProFile

=====

This article last reviewed: 22 December 1988

This article shows you how to use GS/OS with a ProFile hard disk drive.
Before beginning, make sure that:

- The ProFile Interface Card has the 341-0299 ROM. (See Tech Info Library article "GS/OS: Needs Latest ROM Revision To Work With ProFile" for further information.)
- The ProFile Interface Card has been modified for use with the Apple IIGS. (See Tech Info Library article "Apple II ProFile Interface Card Modification for the Apple IIGS" for further information.)

NOTE: The Partition and Zero option of the Advance Disk Utility does not work with the ProFile; it works with SCSI drives only.

Procedure for Using GS/OS With a ProFile

Follow these steps:

1. Select a slot for the ProFile Interface Card (this procedure uses slot 7).
2. Install the ProFile Interface Card and turn on the Apple IIGS.
3. Press Apple-Control-Esc to enter the Control Panel. In the Control Panel, under the SLOTS item:
 - a. Set SLOT 7 to "Your Card".
 - b. Set STARTUP SLOT to "5".
 - c. Press Return, Esc, Return to exit from the Control Panel.
4. Turn the computer off.

5. Insert the Apple IIGS System Disk in the first 3.5-inch drive and the System Tools disk in the second 3.5-inch drive (if available).
6. Turn the computer on.
7. After the system starts up, the SYSTEM.DISK, SYSTEM.TOOLS, and ProFile appear on the desktop.

NOTE: If the ProFile was not formatted for ProDOS, GS/OS asks if the volume should be initialized.

To initialize:

- a. Select "Initialize".
- b. Name the volume.

This should take only a few seconds.

8. Open the System Tools disk and run the Installer program.

NOTE for single-drive systems: Eject the System Disk and insert the System Tools disk. The Installer program prompts you with Eject/Insert dialog boxes.

- a. A list of items to install appears.
- b. Select "Install System Files".
- c. Use the "Volume" button to bring the ProFile disk name to the top right of the screen.
- d. Select "Install".

The Installer program copies the System files from SYSTEM.DISK and SYSTEM.TOOLS disks to the ProFile. Old System files are replaced, but Desk Accessories, Fonts, and other files in "SYSTEM FOLDER" are not deleted.

9. To add other items, such as the SCSI card or 5.25-inch drive:
 - a. Select the item.
 - b. Click Install.

10. Install a printer driver:

- a. Select the item.
- b. Click Install.

11. Set the Control Panel to start up from slot 7.

12. Restart the system using the ProFile.

The ProFile is now set up for use with GS/OS.

NOTE: If you copy applications to the ProFile, copy only the program and data files. Do NOT copy the System Folder from the application

disks.

Compugraphic-to-Macintosh Solutions

Revised: 8/4/89
Security: Everyone

Compugraphic-to-Macintosh Solutions

=====

This article last reviewed: 22 December 1988

There is a relatively easy way to put Macintosh documents through a Compugraphic typesetting machine. TeleTypesetting Company has a product called "MicroSetter II" that works with the Compugraphic MCS 8000, 8400, and 8600 typesetters. Basically, it is a Chooser-selectable printer driver. The Compugraphic typesetter and the Macintosh connect via serial ports.

Most Macintosh applications (including PageMaker, XPress, MacDraw, MacWrite, Microsoft Word, and many more) work with MicroSetter II.

Another solution is a Compugraphic product -- "CG Script" -- a hardware/software package that accepts PostScript files from any Macintosh for direct output on a Compugraphic MCS 8000, 8400, CG 9600 or 9700 typesetting unit.

For more details, search the Tech Info Library for "TeleTypesetting Company" and/or "Compugraphic".

Tektronix Graphics Terminal Emulation for Macintosh II

=====

This article last reviewed: 22 December 1988

Grafpoint markets TGRAF-07 and TGRAF-15LR graphics terminal emulation software for the Macintosh II. These two emulators provide the graphics features available on a Tektronix 4107 or 4115 Graphics Terminal.

Grafpoint TGRAF provides the ability to run hundreds of mainframe applications that previously required a dedicated graphics terminal. For example: CAD/CAM, data analysis and representation, mapping, and molecular design.

TGRAF for the Macintosh II has minimum requirements of one disk drive, Macintosh II Video Card with Video Card Expansion Kit (256 colors required), monitor, communications port, and minimum memory of 2Mb (additional memory increases the amount of segment storage available).

Terminals emulated by TGRAF-07 and TGRAF-15LR include:

- DEC VT52
- DEC VT100
- DEC VT102
- Tektronix 4010
- Tektronix 4014
- Tektronix 4106
- Tektronix 4107
- Tektronix 4109

In addition, TGRAF-15LR emulates:

- Tektronix 4115

For more information, search the Tech Info Library using "Grafpoint".

Static Column DRAM: CAS and RAS

Revised: 2/9/89
Security: Everyone

Static Column DRAM: CAS and RAS

=====

This article last reviewed: 22 December 1988

CAS (Column Address Strobe) before RAS (Row Address Strobe) or vice versa determines whether the column or the row gets referenced first, when the computer is addressing a location in memory. Static column DRAMs have faster memory access (if the architecture supports it). They let the CPU specify only the row address of multiple memory locations in the same column. The first address is addressed by specifying both the row and the column. After this, the column location can be omitted because it is retained. This is why it is called static column DRAM.

AppleShare 2.0.1 and System Software 6.0.2

=====

This article last reviewed: 10 January 1989

Those wishing to update their AppleShare networks with the latest system software (version 6.0.2) may already have updated to the latest AppleShare (version 2.0.1), or may be using a previous version of AppleShare. The following instructions will help with both situations.

To update a server already running AppleShare 2.0.1:

1. Shut down the server.
2. Restart with the System Tools 6.0.2 disk.
3. Launch the Installer.
4. Select the type of computer.
5. Click the Install button.
6. Once installation is complete, click the Quit button.
7. In the Finder, select Restart.

To update the server with both AppleShare Server 2.0.1 AND System Software 6.0.2:

1. Shut down the server.
2. Restart with the AppleShare File Server Installer disk.
3. Launch the Installer.
4. Select AppleShare Server (2.0.1).
5. Click the Install button.
6. Once installation is complete, click the Quit button.
7. In the Finder, select Shutdown.
8. Restart with the System Tools 6.0.2 disk.
9. Launch the Installer.
10. Select the type of computer.
11. Click the install button.
12. Once installation is complete, click the Quit button.
13. In the Finder, select Restart.

GS/OS: SCSI and ProFile Card Compatibility

=====

This article last reviewed: 24 April 1989

If you are using GS/OS version 4.0, you must have the latest versions of the ProFile and SCSI Interface Cards as well. Recent testing results show that GS/OS version 4.0 is compatible with revision C of the SCSI and ProFile cards.

You can determine if you have the required version of these cards by the ROM part number that is installed in the card.

SCSI Interface Card

ROM part number 341-0437 rev. A is the latest ROM for the SCSI Interface Card. When this ROM is installed, it brings the revision of the card up to rev. C. This configuration is compatible with version 4.0 of GS/OS.

ProFile Interface Card

ROM part number 341-0299 rev. B is the latest ROM for the ProFile Interface Card. When this ROM is installed, it brings the revision of the card up to rev. C. This configuration is compatible with version 4.0 of GS/OS.

As of the date of this article, all service ROM inventory is the latest version, and all ProFile and SCSI Interface Cards shipped by service are the rev. C configuration, which is compatible with all Apple II computers.

Apple IIGS

The Apple IIGS requires ROM version 01 to run GS/OS 4.0. To determine if you have the correct version boot the Apple IIGS, at the bottom of the screen should be displayed a copyright line and "ROM Version 01". Contact your dealer for the free upgrade.

Macintosh Plus and SE Require Dynamic RAM

=====

Article Created: 23 February 1989
Article Last Reviewed: 23 June 1992
Article Last Updated:

TOPIC -----

I upgraded the RAM (Random Access Memory) in my Macintosh SE and now I'm having all sorts of video problems.

DISCUSSION -----

Some users have had problems with the Macintosh SE and Macintosh Plus when they install static column RAM rather than dynamic RAM. These two computers can only use dynamic RAM. This explains why:

- The video display is affected, and the operation of the machine is not.
- The SIMMs passed QA at the manufacturer and the SIMM tester at Xerox.
- The same modules worked in the Macintosh II and did not in the Macintosh SE; the Macintosh II can use static column RAM.

Note: the CAT and MacTest SE diagnostic tests on memory do not detect a problem.

AppleShare Print Server Allows Multiuser Access

Revised: 2/6/90
Security: Everyone

AppleShare Print Server Allows Multiuser Access

=====

This article last reviewed: 10 January 1989

The main reason for using the AppleShare Print Server is to allow many users to print documents at the same time. A print server reduces the waiting time by allowing several users to send documents simultaneously to be printed. When used with a LaserWriter printer, PostScript code is sent to the print server and then to the printer. The printer then processes this PostScript code to produce the bit-map graphics at 300 dpi.

When printing to an AppleTalk ImageWriter printer, the computer creates and sends the bit-map image to the printer. Creating this bitmap takes processing time from the computer. Because the computer is having to spend time creating the bitmap, you will not see a major difference in the amount of time it takes to send the data to the printer or the spooler.

When printing directly to a printer, the print driver runs at an even speed with the printer due to data transmission speeds. When connected over AppleTalk, the network runs faster than 19,000 or 9600 baud, but the driver has not been optimized for speed. It keeps up with the speed of the printer. At times, the computer is waiting for the printer to finish printing the line; other times, the printer is waiting for the computer to send and process the line. This is why the 32K option card is not recommended for Macintosh users.

The following table shows the amount of data that is being sent to the ImageWriter LQ printer in all three modes. The following started as a 5.5-page AppleLink document (file size 12,648 or 13K).

Amount of data transferred to the print server or the printer:

Best Mode	Faster	Draft
-----	-----	-----
578K	127K	43K

The increased size of the Draft is due to AppleTalk overhead (establish

session, packet overhead). The Faster file sends out a 72-dpi bitmap in GRAPHICS mode of the ImageWriter LQ. The Best mode sends out a 216-dpi bitmap. This takes up more space and requires more time to send the data to the printer or spooler. If the driver could create the 578K faster, the print server would be able to store the data faster. However, most of the time, the print server is waiting for the computer to send out the data.

Macintosh System 6.0: How Desk Accessories Function

=====

Article Created: 10 January 1989
Article Last Reviewed: 28 May 1992
Article Last Updated: 28 May 1992

The following information is relevant only for system software version 6.0.X.

TOPIC -----

I heard that many existing desk accessories (DAs) from previous versions of the system software will not function correctly under System 6.0.X, especially when running MultiFinder.

DISCUSSION -----

Desk accessories function as they always have under previous system versions. A correctly-written DA will function normally under system software 6.0.X. The one exception is when desk accessories are called under MultiFinder.

Desk accessories are DRVR resources and do not have, nor are they, CODE resources. They can exist in open files in the System Folder and be picked up when the drivers are called by an application or the Finder for display in an Apple menu. The Apple menu resides in the System ROMs, and the DA list is created by an application or by the Finder.

A change that may affect a DA is the loading of desk accessories into the System heap. Desk accessories expecting to load into a specific application heap will not function under the new system software. In the cases of these application-specific and application-dependent desk accessories, the DA will not know which application heap called it (since there could be multiple application heaps).

The System has been patched to allow desk accessories to function within an application-like environment belonging to the System. The environment is called DA Handler. The DA Handler is a level of the System that executes desk accessories when called. This is to allow all desk accessories to come to the

foreground when a DA is selected, rather than having to select the application the DA belongs to. This also allows the System to control the Apple menu, allowing selection of applications as well as desk accessories.

Macintosh SE 2/40: How To Configure for 2.5MB RAM

=====

Article Created: 29 November 1988

Article Change History

9/15/92 - REVIEWED
• For technical accuracy.

TOPIC -----

How do I configure a Macintosh SE for 2.5MB of RAM? I've heard there's a jumper on the logic board that needs to be removed.

DISCUSSION -----

To properly configure the Macintosh SE 2/40 (or any Macintosh SE with a RAM configuration jumper labeled "2/4MB to 1MB") for 2.5MB, the jumper must be completely removed.

Apple suggests leaving the jumper connected to one pin so that it is available for future upgrades.

NOTE: The RAM configuration for the Macintosh SE 2/40 is the OPPOSITE of previous Macintosh SE and Macintosh Plus systems. The highest capacity SIMMs occupy sockets 3 and 4 on the newer boards with the jumper RAM configuration. Older boards with the solder configuration require the highest capacity SIMMs to occupy sockets 1 and 2.

Apple IIe: AppleTalk Workstation Card and Printing

=====

This article last reviewed: 29 November 1988

To print to a serially-connected ImageWriter through the AppleTalk Workstation Card on an Apple IIe:

1. Place the AppleTalk Workstation Card in any Apple IIe slot.
2. Start up the system with the Workstation disk. (If there are no disks in the drives, the system starts up over the network with a slight delay.)
3. Select Chooser.
4. Using the Chooser, select the locally-connected serial printer. (Local printers and AppleTalk printers are shown on separate lists.)
5. Ensure that the printer is connected to the printer port on the AppleTalk Workstation Card.
6. Set the application to print to the slot that the Workstation Card is in.

Apple II Workstation Card: Printing Via a Serial Port

=====

This article last reviewed: 7 December 1988

If you want to run Apple II Workstation Cards on a network, and also want to have some workstations' printers directly connected to the serial port on the Workstation card, try the following solution:

Install the card in slot 7 on the Apple II.

Run the new Chooser II (ver. 1.2.1) software. When the Apple II WorkStation Card is installed, a new option window appears in the lower righthand corner that allows the output to be directed to either the serial port or the AppleTalk port on the card. Once the serial port is selected, everything should work perfectly.

Apple Scanner and EPS Files

=====

This article last reviewed: 29 November 1988

To use AppleScan images outside the TIFF and PICT file formats, copy the AppleScan image and paste it into the application you are using.

To save AppleScan images in EPS (Encapsulated PostScript) requires an additional program that supports either the TIFF or PICT file format and the EPS file format. Open the AppleScan file (TIFF or PICT) and save it as EPS.

TIFF and PICT are recognized as the standard for scanned images. Currently, Freehand 1.0 from Aldus Corporation is the only major program using scanned images that does not accept TIFF or PICT. (Freehand 2.0, which was recently announced, does support both PICT and TIFF.)

(NOTE: A disadvantage of scanned images in EPS file format is that they tend to be larger than the same scanned images in TIFF or PICT.)

For more information, search under: "Aldus".

GS/OS and High ASCII Character Codes

Revised: 9/22/89
Security: Everyone

GS/OS and High ASCII Character Codes

=====

The GS/OS (version 4.0) operating system does not interpret keystrokes; the extended character sets are handled by the firmware of the Apple IIGS itself. The firmware directly understands only the lower 128 ASCII codes. To access symbols assigned above the lower 128 codes requires examination of the ADB information. No extended characters are recognized automatically.

The Command key (Open-Apple) or Option key (Closed-Apple) can be detected via PEEKs of the game port buttons or via the keyboard modifier returned by GetNextEvent. By checking for these keys, then checking the character key, the programmer is able to assign one of the extended characters to the Command-X or Option-X keystroke.

Apple IIGS: Remote Access To AppleShare via InterBridge

=====

This article last reviewed: 7 December 1988

If you have more than one Apple IIGS on a Macintosh server using AppleShare, and you want dial-in service from a remote Apple IIGS, one solution is to use an InterBridge, manufactured by Hayes Microcomputer.

The InterBridge allows two networks, each equipped with an InterBridge and a Hayes Smartmodem, to access each other through either dial-up or leased telephone lines.

Initially, a Macintosh needs to be connected to the remote network to configure the remote InterBridge with the Hayes set-up/admin software, but the Macintosh can be removed when the configuration is complete.

Security: Everyone

Macintosh: How To Unlock Locked Volumes

=====

Article Created: 8 December 1988
Article Last Reviewed: 14 July 1992
Article Last Updated: 14 July 1992

TOPIC -----

My hard drive says that it is locked (and I haven't locked it myself). It won't allow me to make any changes to the disk.

DISCUSSION -----

There is a specific bit in the volume information header that causes a volume to be locked (a result similar to what happens to a floppy with the locking tab open). You can change this bit's value by using a low-level disk editor, such as FEdit Plus, Norton Utilities, or Symantec Utilities from Symantec Corp.

IMPORTANT: Don't do this on a disk that isn't backed up. Also, if you don't find the 8000 located at the tenth byte in that specific sector, get higher-level help.

Once you have started up your disk editor:

1. Open the hex representation of the volume that has the problem.
2. Go to sector number 2. (This should be the third sector on the disk with each sector having a length of 512 bytes.)
3. The sector should look something like this:

```
4244 9FAE F13C 9FAF 228B 8000 0010 0003
0000 063A 0000 0200 0000 0800 0004 0000
0020 0488 0855 6E74 6974 6C65 6400 0000
```

...and so on, where the 4244 begins at the zero byte of the sector.

4. The key location is where you see the word containing 8000. It should be

located at the tenth byte.

5. If the 8000 is at the tenth byte, change it to 0000 and write the sector to disk.
6. You will have to restart the system to have the change take effect, since this information is usually stored in memory and won't be updated until you restart.

On a related note, if you are running System 7 and you are simply not able to rename your hard disk (though writing to it does work fine), check to make sure file sharing is turned off. Even if you do not set the sharing permissions for a particular volume, file sharing still makes all volumes available to the owner for remote access. To change the name of a mounted volume, turn file sharing off with the Sharing Setup control panel, rename the disk, then turning file sharing back on again.

LocalTalk PC Can Print Directly To LaserWriter IINT

Revised: 5/24/89
Security: Everyone

LocalTalk PC Can Print Directly To LaserWriter IINT

=====

This article last reviewed: 8 December 1988

If you wish to print from IBM PC applications such as Windows, it is best to have AppleShare PC installed on your system.

If AppleShare PC is not installed, the LocalTalk Card prints only with the LaserWriter Print program. If you use AppleShare PC, then the connected LaserWriter outputs whatever is printed to the selected printer port.

The printer port is attached to the LaserWriter in the DA application. Almost any application that prints with an Apple LaserWriter PostScript driver can print to the LaserWriter connected with a LocalTalk PC card and AppleShare PC.

An application, DOS, or Windows has to be set for the same printer port as the DA application in its printer configuration parameters. If an application does not have an Apple LaserWriter PostScript driver, the DA can convert Epson printer driver output to PostScript and send that out to the LaserWriter.

Apple has tested Microsoft Word and Windows, and has found them to work when configured properly with the AppleShare PC software and LocalTalk PC card on an IBM AT.

Printing is dependent on the driver used and the port being printed to. This is usually handled by an application.

Printing can be facilitated by Windows. Windows-compatible applications can use the Windows printer drivers. This requires the printer setup for printer port and driver to be designated in Windows instead of the application or from DOS.

Most IBM PC applications should work with the LocalTalk PC Card and AppleShare PC, assuming Epson or Apple LaserWriter PostScript printing is available to the application.

LaserWriter IINTX: Serial to LocalTalk Using PostScript (2/95)

Revised: 2/21/95
Security: Everyone

LaserWriter IINTX: Serial to LocalTalk Using PostScript (2/95)

Article Created: 4 March 1990
Article Reviewed/Updated: 21 February 1995

TOPIC -----

This article describes how to switch from LocalTalk to serial using PostScript.

DISCUSSION -----

After you have switched the LaserWriter IINTX from LocalTalk to serial connection with a PostScript program, you can switch back to LocalTalk again with the following procedure.

Caution:

If you choose to use the PostScript code provided in this article, you assume all risks involved in making these changes. PostScript code, if not entered correctly, can place the LaserWriter into a condition requiring service.

To select AppleTalk PostScript:

%=====

```
% Begin      PostScript Code
%
serverdict begin 0 exitserver %Exits the printer server loop.
statusdict begin           %Starts modifying settings.
2 sethardwareiomode        %Sets communications mode to AppleTalk.
end                         %End of the mode switch routine.
systemdict/quit get exec   %System start test page.
(Control-Z)                %(Keyboard Control key and Z key together)
%                           Ends text editing and saves the file.
%
% End PostScript Code
%=====
```

To select RS-232 PostScript:

```
%=====
% Begin      PostScript Code
%
serverdict begin 0 exitserver %Exits the printer server loop.
statusdict begin              %Starts modifying settings.
0 sethardwareiomode           %Sets communications mode to serial.
9 0 3 setsccbatch             %Turns off the RS-422, 9600-baud port.
25 9600 68 setsccbatch        %Sets the 25-pin, RS-232, 9600-baud port
                                %to 8 data bits.

end                            %End of the mode switch routine.
systemdict/quit get exec      %System start test page.
(Control-Z)                   %(Keyboard Control key and Z key together)
%                               Ends text editing and saves the file.
%
% End PostScript Code
%=====
```

Apple IIGS: Making Disk II Work in Slot 1, 2, or 3

=====

This article last reviewed: 14 December 1988

Some Apple IIGS users have discovered that Disk II drives do not work properly when the controller card is installed in slot 1, 2, or 3. On startup in this configuration you will get an "UNABLE TO LOAD ProDOS" error message.

The reason is that there is some special hardware that was designed into the Apple IIGS just to take care of handling Disk II access. The hardware recognizes Disk IIs, and when an access is attempted, the system switches into slow mode on recognition of the Motor Start signal.

This causes the "UNABLE TO LOAD ProDOS" error, since the system cannot switch speeds quickly enough to begin reading the beginning of the boot blocks on the disk. This is one of the time-critical functions of ProDOS, and it does not function correctly. The problem occurs only when using Disk IIs and only when in the lower numbered slot 1, 2, or 3. This follows the Pascal convention of no bootable devices lower than slot 4.

Here is a workaround:

If the system is running in Slow mode when the access to the Disk II is performed, the boot blocks are read correctly, and the system starts up. The same is true for cataloging the disks.

If you can run your program in slow mode, then you can use the Disk IIs in slot 1, 2, or 3. If not, then you must install the Disk II in slot 4, 5, 6, or 7.

LaserWriter IINT & IINTX Store HandShake Options Differently

Revised: 3/4/90
Security: Everyone

LaserWriter IINT & IINTX Store HandShake Options Differently

=====

This article last reviewed: 14 December 1988

The LaserWriter IINT component that registers the handshake options can wear out with excessive use. This is not true with the LaserWriter IINTX, since the two printers store handshake options differently.

The component in the LaserWriter IINT that can wear out is an EEROM. This EEROM may be written approximately 10,000 times before breakdown.

The LaserWriter IINTX employs a 2K battery-backed-up ZPRAM (Zero Power RAM) equivalent to the EEROM of the LaserWriter IINT. This ZPRAM may be written to an indefinite number of times.

AppleShare Print Server (v2.0): Purpose Is Not Faster Printing

Revised: 2/6/90
Security: Everyone

AppleShare Print Server (v2.0): Purpose Is Not Faster Printing

=====

This article last reviewed: 15 December 1988

Here are some questions about AppleShare Print Server (v2.0):

1. The spooler is only slightly faster than printing directly. Isn't spooling supposed to release the workstation sooner than printing directly would?
2. If multiple users are spooling to the ImageWriter LQ at the same time, will performance decrease significantly?
3. Should we expect performance to decrease if the LaserWriter spoolers are used concurrently?

Specific answers to these questions are at the end of the article.

The main reason for using the AppleShare Print Server is to allow many users to print documents at the same time. A print server reduces the waiting time by allowing several users to simultaneously send documents to be printed. When used with a LaserWriter, PostScript code is sent to the print server and then to the printer. The printer then processes this PostScript code to produce the bit-map graphics at 300 dpi.

When printing to an AppleTalk ImageWriter, the computer creates and sends the bit-map image to the printer. Creating this bitmap takes processing time from the computer. Because the computer is having to spend time creating the bitmap, you do not see a major difference in the amount of time it takes to send the data to the printer or the spooler.

When printing directly to a printer, the print driver runs at an even speed with the printer due to data transmission speeds. When connected over AppleTalk, the network runs faster than 19,000 or 9600 baud, but the driver has not been optimized for speed: instead, it keeps up with the speed of the printer. Some times, the computer is waiting for the printer to finish printing the line; other times, the printer is waiting for the computer to

send and process the line. This is why the 32K option card is not recommended for Macintosh users.

The following table shows the amount of data that is being sent to the ImageWriter LQ in all three modes. The following started out as a 5.5-page AppleLink document (file size 12,648 or 13K):

Amount of data transferred to the Print Server or the printer:

Best Mode	Faster	Draft
-----	-----	-----
578K	127K	43K

The increased size of Draft is due to AppleTalk overhead (establish session, packet overhead). The Faster file sends out a 72-dpi bitmap in GRAPHICS mode of the ImageWriter LQ. The Best mode sends out a 216-dpi bitmap. This takes up more space and requires more time to send the data to the printer or spooler. If the driver could create the 578K faster, the print server would be able to store the data faster; but, most of the time, the print server is waiting for the computer to send out the data.

Answers to questions:

1. The spooler is not slow; it is the Macintosh that cannot send the bitmap to the printer fast enough. The AppleShare Print Server allows multiple users to print at the same time without waiting for the printing resource to become available. The print server does not release the workstation faster when the computer has to process the bitmap.
2. If multiple users are sending documents to the spooler, you do not see any significant decrease, depending on the LocalTalk traffic.
3. Performance does not decrease significantly when you add additional devices to be spooled.

Macintosh OS and A/UX Virtual Memory

Revised: 9/3/92
Security: Everyone

Macintosh OS and A/UX Virtual Memory

=====

Article Created: 23 February 1989
Article Last Reviewed: 31 August 1992
Article Last Updated : 31 August 1992

TOPIC -----

Macintosh OS and A/UX Virtual Memory

DISCUSSION -----

A Macintosh application that requires a large amount of memory under the Macintosh OS can, in some circumstances, run in a smaller memory size under A/UX by taking advantage of virtual memory.

A/UX is a multitasking, 32-bit, virtual memory operating system. Theoretically, you can have applications make memory allocation requests greater than the existing physical memory size as long as the disk space reserved for paged-out memory (the swap space) is not full.

In the Macintosh OS environment, the Macintosh memory management tools are designed for control of a known amount of physical memory; some of the Macintosh memory manager functions don't make sense under virtual memory.

In a virtual memory environment, such as A/UX, it's not clear what value the call to determine the amount of free memory available should return. In the current implementation of A/UX Toolbox in A/UX 1.0, memory query routines such as FreeMem respond as if the application had a 1MB chunk of free memory.

If the Macintosh OS application program in question was rewritten so that memory allocation routines, like NewPtr and NewHandle, did not request more than 1MB at a time, then it should run OK under A/UX.

An application can continue to allocate 1MB chunks as needed, and A/UX will respond by using virtual memory. For example, the Macintosh OS application could allocate 1MB chunks of memory 10 times (10MB in total exceeds Macintosh II's 8MB maximum memory size), which should run without any problem under A/UX.

In A/UX 3.0, virtual memory is configurable in the memory control panel.

AppleShare 2.01: Maximum Number Of Files

Revised: 2/6/90
Security: Everyone

AppleShare 2.01: Maximum Number Of Files

=====

This article last reviewed: 15 December 1988

With AppleShare 1.1, volumes should contain no more than 8,000 files due to the PDS problems.

The PDS problem was fixed in version 2.01 of AppleShare and, thereby, removed the recommended 8,000-file limitation. AppleShare 2.01 is now limited by the number of files allowed under HFS.

It is sometimes noted that HFS is limited to 64,000 files per volume. This is not strictly correct, though it may be true in practice.

A count of the total number of files and directories on the volume is maintained, as a LongInt, in the MDB (block 2). Directory IDs are also LongInts. This limits the number of files and folders on the volume to $2^{32}-1$ (roughly 4.3 billion). That many folders could be created as long as there's room on the volume to hold the expanding catalog B*-Tree.

Because each file occupies at least one allocation block, all of the--at most--65,536 allocation blocks (also numbered by Integers) will be allocated just before that many files are written on the volume, so the limit of 64,000 files is close to the practical limit.

There is another limitation imposed: a directory's valence is an Integer and, furthermore, on GetCatInfo requests, any negative number in the ioFlIndex field is interpreted as a request for information on the directory itself. So, while HFS allows the creation of up to 65,536 files in each directory, all of which can be accessed by name, only 32,767 can be enumerated -- a real limitation on folder contents. In practice, the user's patience will run out well before this many items can be enumerated.

Finally, all computations on file sizes are performed using LongInts, so there's no practical limit on the size of an individual file -- though the actual limit is about two gigabytes.

Apple Scanner: Tips and Hints

Revised: 5/24/89
Security: Everyone

Apple Scanner: Tips and Hints

=====

This article last reviewed: 15 December 1988

Here are some tips on working with the Apple Scanner:

The most common problem users may have is a system error when saving a file that has been scanned. This occurs when the current brightness and contrast settings or half-tone pattern name exceeds 17 characters, usually because the default setting name "Untitled Settings" is saved. The next time changes are made to the brightness or contrast, the settings' name changes to "Untitled Settings 2", which violates the rule. Delete all setting names that are too long, and the problem is fixed.

Here are some hints about cutting and pasting. AppleScan fully supports cut-and-paste to the Clipboard and other AppleScan documents. Grayscale data, however, cannot be intermixed with line art or halftones in the same document. It's okay to have line art and halftones in the same document, though.

A neat feature is to copy a region of a document, then use the selector tool to select a differently sized region, and paste into the region. This works best with Grayscale data. Also, try pasting with the Tab key held down. This invokes a transparent paste.

AppleScan, however, is not intended to be an "integrator" of data from other sources. Data from other programs (text, Paint, or PICT), when pasted into AppleScan, do not behave like a MacDraw-type environment, and using AppleScan in this way is not recommended. Instead, AppleScan should be used as a source of scanned data, which are then moved to other applications that are better suited for those tasks.

(NOTE: Pasting data from MacDraw II creates a strange effect on the Macintosh screen, but does not appear to cause a fatal error.)

AppleScan can save data in the PICT, TIFF, and Paint file formats. However, if a document is saved in the TIFF format and changes are made

to the file, a "Do you want to save changes?" prompt appears when the document is closed. If changes are saved, the file type changes to PICT format. This is a known problem.

Finally, if the user quits AppleScan with the Remote Scan option selected and then goes to HyperScan and clicks on the Preview or Scan button, the scanning will not start until the remote button on the Apple Scanner is pressed. Remote scanning is not reset when quitting AppleScan. This, too, is a known problem.

(NOTE: "Remote" is reset when AppleScan is started.)

AppleShare File Server 2.0.1 and Macintosh SE/30

Revised: 2/6/90
Security: Everyone

AppleShare File Server 2.0.1 and Macintosh SE/30

=====

This article last reviewed: 22 June 1989

When using the Macintosh SE/30 as an AppleShare 2.0.1 File Server be aware of the following:

1) Do not use the System Files on the AppleShare Server Installer Disk. First install 6.0.3 and then install the AppleShare File Server from the Server Installer Disk. Don't select both System Files and AppleShare File Server from the Server Installer Disk. This is contrary to the AppleShare manual (page 35).

2) After you quit from the Server Installer Disk and select RESET or RESTART from the Finder, the system hangs. This is a problem in the Installer and 030 machines that appears when you are not using System 6.0.3. The Server Installer Disk does not use System 6.0.3 and should not be updated.

3) If running a Macintosh IIX or Macintosh SE/30 as a server, you should use 6.0.3 to avoid file server crashes.

4) If your server is crashing, make sure you are running System 6.0.3 or later.

5) Do not use Appleshare 1.0 or 1.1 on a Macintosh SE/30 or Macintosh IIX.

Macintosh SE/30: Doesn't Work With An Apple Hard Disk 20

=====

Article Created: 18 January 1989

Article Change History

9/15/92 - REVIEWED
• For technical accuracy.

TOPIC -----

Can I use the Hard Disk 20, which is a non-SCSI hard drive, with the Macintosh SE/30?

DISCUSSION -----

The Hard Disk 20 (Non-SCSI) does NOT work with the Macintosh SE/30. The code to support the drive is not included in the ROM of the Macintosh SE/30. To transfer data from a Hard Disk 20 to the Internal drive you need the following items:

- Macintosh Plus or Macintosh SE
- Formatted, blank Hard Disk 20,40,80 SC and cables
- System 6.0.3 Tools Disk (included with the Macintosh SE/30)

- 1) Hook up the Hard Disk 20 and the Hard Disk 20, 40, 80 SC to the Macintosh Plus or SE.
- 2) Insert the System Tools disk in the internal drive.
- 3) Turn on both drives, wait 10 seconds, and then turn on the computer.
- 4) Use the Find File DA and look for a file called SYSTEM on the Hard Disk 20.

- 5) There should be one file called SYSTEM, and it should be located in the SYSTEM FOLDER. If you have more than one SYSTEM file, return to the desktop and trash the other system files from the Hard Disk 20.
- 6) Select all the files and folders on the Hard Disk 20 and any files that may be on the desktop and drag them to the Hard Disk 20, 40, 80 SC.
- 7) After the copy is finished you can hook up the Hard Disk 20, 40, 80 SC to the Macintosh SE/30.
- 8) Select the files from the Hard Disk 20, 40, 80 SC and drag them to the internal hard drive. If there is no internal hard drive, drag them to the drive you will be using.
- 9) Update the System Files to System 6.0.3 using the Installer Script (located on the System Tools Disk) for the Macintosh SE/30.

9/15/92 - REVIEWED

- For technical accuracy.

TOPIC -----

This article describes the Macintosh SE/30.

DISCUSSION -----

The Macintosh SE/30 follows the same user-friendly philosophy as the original Macintosh, while providing more memory, faster performance, and greater expandability. The Macintosh SE/30 provides all the power of the Macintosh IIX, except NuBus, within a smaller footprint.

The Macintosh SE/30 was designed for users who demand both peak performance and transportability. It extends the family by improving performance and maintaining compact design. The Macintosh SE/30 offers three to four times the computational power of the Macintosh SE and demonstrates Apple's commitment to refining the original Macintosh design.

The Macintosh SE/30 contains the following:

- MC68030 processor running at 15.6672 MHz
- MC68882 floating point co-processor
- Apple SuperDrive (formerly Apple FDHD) 1.4MB, only one internal floppy drive supported
- Internal 50-pin SCSI connector for a 3.5-inch hard disk
- Apple Sound Chip stereo output support through the rear audio port
- 030 Direct Slot for third-party expansion products

..TIL03502-Macintosh_SE-30-General_Description_Discontinued.pdf

- ROMM SIMM using the same ROMs as the Macintosh IIX
- Same power supply, video board, and CRT as the Macintosh SE

9/15/92 - RETITLED

- To reflect emphasis on compatibility with DIP SIMMs.

9/15/92 - REVIEWED

- For technical accuracy.

TOPIC -----

Can I use DIP (tall) SIMM strips inside the Macintosh SE/30?

DISCUSSION -----

Like the Macintosh IIX, the Macintosh SE/30 contains two banks of SIMM sockets, Bank A and Bank B. Each bank holds four SIMM strips. Due to space restrictions inside the case, Bank B can only use the PLCC/SOJ (low-profile) SIMM strips.

WARNING

If you use DIP (tall) SIMM strips you will have problems with the logic board touching the lower case. This may cause the logic board to short out. DO NOT USE TALL SIMM STRIPS IN BANK B.

The following are valid memory configurations:

1MB - Bank A 4 256K SIMMs
Bank B Empty

2MB - Bank A 4 256K SIMMs
Bank B 4 256K SIMMs low-profile

4MB - Bank A 4 1MB SIMMs

Bank B Empty

5MB - Bank A 4 1MB SIMMs

Bank B 4 256K SIMMs low-profile

8MB - Bank A 4 1MB SIMMs

Bank B 4 1MB SIMMs low-profile

Macintosh SE/30: Specifications (Discontinued 10/90)

Article Created: 18 January 1989

TOPIC -----

This article gives the specifications for the Macintosh SE/30.

DISCUSSION -----

CENTRAL PROCESSING UNIT (CPU)

- Microprocessor : 15.6672 MHz MC68030 CPU
- Address Bus : 32-bit
- Registers (32-bit) : 16 general-purpose data and address, two 32-bit Supervisor stack pointers, ten special-purpose control registers
- Addressing Modes : 18
- 256-byte instruction cache and 256-byte data cache
- Built-in Paged Memory Management Unit (PMMU)

COPROCESSOR

- MC68882 floating-point unit (follows IEEE standards)

MEMORY

- 1, 2, 4, 5, 8MB RAM (Random Access Memory)
- 256Kbytes of ROM (Read-Only Memory)
- 256 bytes of settable parameter memory with built-in battery backup

DISPLAY

- Built-in, 9-inch diagonal, 512 by 342 pixel, black and white monochrome monitor (no gray scale)

KEYBOARD (not included)

- Apple Keyboard or Apple Extended Keyboard can be connected through the Apple Desktop Bus port

MOUSE

- Apple Desktop Bus Mouse (ADB) mechanical tracking, optical shaft or contact encoding 100 +/- 10 pulses per inch (3.94 +/- 0.39 pulse per mm)

of travel

DISK DRIVE

- One Apple SuperDrive (formerly Apple FDHD) 1.4MB high-density internal drive. Only one internal floppy drive is supported; the unit ships with the Apple SuperDrive, but the logic board also supports an 800K drive.
- External connector for 800K

HARD DISK DRIVE

- A 3.5" 40MB or 80MB hard drive is standard.

INTERFACES

- Two Apple Desktop Bus (ADB) connectors for keyboard, mouse, and low-speed input devices
- 030 Direct Slot supporting full 32-bit address and data lines through a 120-pin Euro-DIN connector
- Two RS-232/RS-422 serial ports, 230.4K baud maximum (up to 0.920 Mbit per second, if clocked externally)
- SCSI interface
- Stereo sound port for external audio amplifier

SOUND GENERATION

- Apple Sound Chip (ASC) including 4-voice, wave-table synthesis and stereo sampling generator, capable of driving stereo mini-phono jack headphones or stereo equipment
- Mixed stereo monophonic sound output through internal speaker

ELECTRICAL REQUIRMENTS

- Line voltage: 85 to 270 volts AC
- Line frequency: 47 to 63 hertz
- Maximum power consumption: 76 watts continuous, 99 watts maximum for 15 seconds 10% duty cycle

ENVIRONMENTAL REQUIREMENTS

- Operating temperature: 50 TO 95 degrees F (10 TO 35 degrees C)
- Storage temperature: -40 TO 116.6 degrees F
- Relative humidity: 5% to 95% (noncondensing)
- Altitude: 0 to 10,000 ft (0 to 3048 m)
- Fan: 10 CFM radial

SAFETY AND EMI QUALIFICATIONS

- FCC part 15 Class B Computing Devices
- UL 11 Office Appliances and Business Equipment

SIZE AND WEIGHT

Main Unit

- Height: 13.6 inches (345.4 mm)
- Width: 9.6 inches (243.8 mm)
- Depth: 10.9 inches (276.2 mm)
- Weight: 19.5 lb. (9.75 kg)

Apple Keyboard (not included)

- Height: 1.8 inches (44.5 mm)
- Width: 16.5 inches (418.3 mm)
- Depth: 5.6 inches (142.0 mm)
- Weight: 2 lb. 2oz. (1 kg)

Apple Extended Keyboard (not included)

- Height: 2.3 inches (56.4 mm)
- Width: 19.1 inches (486 mm)
- Depth: 7.4 inches (188 mm)
- Weight: 3lb. 10 oz. (1.6 kg)

Apple Mouse (ADB)

- Height: 1.1 inches (27.9 mm)
- Width: 2.1 inches (53.3 mm)
- Depth: 3.8 inches (96.5 mm)
- Weight: 6 oz. (.175 kg)

Macintosh System Software Version 6.0.3: Who Needs It

Revised: 8/22/91
Security: Everyone

Macintosh System Software Version 6.0.3: Who Needs It

=====

Article Created: 18 January 1989
Article Last Reviewed: 22 August 1991
Article Last Updated: 22 August 1991

TOPIC -----

This article explains the changes made in system software version 6.0.3, and how it improves support for certain software and hardware.

DISCUSSION -----

Macintosh SE/30 requires System 6.0.3. The following are the only changes in 6.0.3:

- 1) Patched the .SONY driver to fix a tolerance problem when initializing MS-DOS disks. This problem would show up when you formatted a MS-DOS disk on an Apple SuperDrive (formerly Apple FDHD) and then used the disk on a PC. If you formatted this disk on the PC you did not see any problem.
- 2) Placed a hook in the System File that lets a file called "32-Bit QuickDraw" attach itself to the System file. We are not supplying the "32-Bit QuickDraw" file, only the ability to add the file at a later date.
- 3) Time Manager upgraded to work with the Macintosh SE/30.
- 4) Removed the NewYork 18 and 24 from the disk for space reasons.
- 5) Changed the Responder INIT to return the names "Macintosh SE/30" and "Macintosh IIX" when used with Inter-Poll.
- 6) Apple File Exchange had some bugs fixed.

Network users do NOT need to upgrade any other machines on the network. You can use System 6.0.3 on other machines but you do not HAVE to upgrade other network users unless you want to. There were NO changes to the AppleTalk

protocols or Printer Drivers. Had they changed, other network users would need to be upgraded.

The following are the only users who should upgrade to System 6.0.3:

- Owners of Macintosh SE/30 computers
- People who use Apple File Exchange (on any Macintosh CPU)
- Users of 24-bit color boards, when the 32-bit QuickDraw file becomes available

MacWorkStation 3.1: Introductory Information

Revised: 8/25/89
Security: Everyone

MacWorkStation 3.1: Introductory Information

=====

This article last reviewed: 23 August 1989

MacWorkStation 3.1 is an upgrade to version MacWorkStation 3.0. The goal of the new version is to increase ease of use, make the software more powerful and robust, and add support for new hardware capabilities of the Macintosh, such as color and multiple monitors. MacWorkStation 3.1 also supports system software such as MultiFinder, hierarchical and pop-up menus, mixed font sizes and styles in text, and AppleShare permission values.

Apple has two utilities that can be used with MacWorkStation: Event Handler and Dialog Builder. These are described in the last section of this document.

MacWorkStation 3.1 is compatible with MacWorkStation 3.0. Developers will not need to change their programs, unless they want to take advantage of the new features of the 3.1 version. Current licensees of MacWorkStation 3.0 will receive free upgrades to 3.1.

Positioning

Apple is positioning MacWorkStation as an "application server," which provides Macintosh application services to client software running on a remote computer. When discussing MacWorkStation, Apple will now use the terms server and client in the same way that X Windows developers use these terms. The application server software is the MacWorkStation software that runs locally on the Macintosh, providing services to remote client software that will be written by customers and third party developers on a variety of host computers. Services offered by MacWorkStation include local printing, filing, and editing, and access to Macintosh user interface objects such as windows, pull-down menus, and dialog boxes.

Apple is re-positioning MacWorkStation as a developer tool, rather than a communications tool. MacWorkStation supports a variety of communications protocols, including RS-232, AppleTalk, Ethernet, 3270, etc. However, the communications abilities of MacWorkStation are not what make MacWorkStation

such an important product. More significant is the fact that it provides a standard Macintosh user interface to client applications running on remote host computers. MacWorkStation is appropriate for customers who wish to develop Macintosh user interfaces to host programs, without doing any Macintosh programming. To use MacWorkStation, a host programmer must add software to the host program to send commands to the MacWorkStation software running on a Macintosh. The MacWorkStation server software running on the local Macintosh presents menus, windows, lists, and other objects to the user based on the content of the commands sent by the client host software. The MacWorkStation software running on the Macintosh will also handle all local editing, printing, and filing.

MacWorkStation can run transparently over a variety of communication protocols because the low-level communications services are provided by Macintosh code segments (called communications modules) that are added to MacWorkStation at run time. Communications modules already exist for RS-232 and AppleTalk. Apple is working on additional modules for the AppleLine and 7171 protocol converters, LU 6.2, and TCP/IP. Third party developers are also working on communications modules. For example, both Avatar and DCA are working on 3270 communications modules.

Availability

MacWorkStation 3.1, Event Handler, and Dialog Builder are available from APDA. The communications modules is packaged as a separate APDA product.

Enhancements included in MacWorkStation 3.1

- Graphics support - RGB Color is supported in alerts, cursors, dialog boxes, dialog items, patterns, pictures, text, and windows. The MacWorkStation 3.1 graphics director provides faster redrawing and scrolling of complex pictures.

- HFS and AppleShare support - MacWorkStation 3.1 fully supports the hierarchical file system calls. In order to support AppleShare directories and files, permission values can be set and retrieved, and byte ranges in a file can be locked.

- Improved list management - The list director has been extended to provide field level editing in addition to the record level editing provided in older versions of MacWorkStation. A new command has been included to allow the remote application to read only those records that have been modified. The host can now specify that records be sorted in either ascending or descending order based on any field or combination of fields. The sort can also be done by a local menu command.

- Improved error detection at the presentation level - Earlier versions of MacWorkStation ignored invalid commands or parameters, making it difficult for developers to debug problems. MacWorkStation 3.1 provides optional command and parameter syntax checking. The host program can specify what action should be taken if any errors are encountered in the command data stream.

- Event locking and unlocking - Because MacWorkStation applications communicate with a remote host, sometimes the user will think that a mouse selection didn't work, when really the reaction from the host is just taking a long time to get to the Macintosh. In this case, users will often re-select or re-type a field, causing the host to have to do even more work. With MacWorkStation 3.1, the host can specify that MacWorkStation should make the cursor a watch to indicate that the data is being processed. MacWorkStation will go into an "event lock" state until the host sends more data. This new feature of MacWorkStation 3.1 was added in response to problems reported by early users of MacWorkStation 3.0.

New Utilities

Event Handler is a new MacWorkStation Exec module which provides local nonprocedural scripting for responding to MacWorkStation events. Event Handler is an excellent utility for prototyping MacWorkStation programs. During the prototyping phase, a developer can use Event Handler to emulate what a host will do in the final version, without really having a host connected. It will also be very useful for final programs because it can respond to events generated by the user without sending a transaction to the remote host computer. This would be appropriate for standard and consistent events such as cancel buttons or help buttons, where host interaction isn't required. (Event Handler is an enhanced version of the beta Script Writer software that some early users of MacWorkStation may have already used. Event Handler may not be the final name that is chosen for this Exec module.)

Dialog Builder is a utility program that provides a powerful and easy method for quickly building dialog boxes for MacWorkStation 3.1. Users familiar with MacPaint or MacDraw will appreciate the object palette, which can be used to draw dialog boxes. The dialog box that is drawn can be stored in a MacWorkStation document for later recall by the remote client application. MacWorkStation dialog director commands can also be created and transferred to the remote host to be used when a MacWorkStation application is running. Dialog Builder is an enhanced version of the beta RezPaint software that some early users of MacWorkStation may already have used.

Security: Everyone

Macintosh IICx: General Description (Discontinued)

=====

Article Created: 7 March 1989
Article Last Reviewed: 10 July 1992
Article Last Updated: 22 August 1991

TOPIC -----

This article describes the Macintosh IICx.

DISCUSSION -----

The Macintosh IICx computer is a modification of the Macintosh IIX design that uses a Motorola MC68030 microprocessor and a MC68882 numerics coprocessor. The Macintosh IICx uses the Apple SuperDrive (formerly Apple FDHD) 1440K floppy drive.

Because the Macintosh IICx is the first computer that Apple has produced with this physical form factor, there will not be an upgrade kit for any of the current members of the Macintosh family to the IICx.

MC68030

The Macintosh IICx uses the Motorola MC68030 at 15.6672 MHz, the same speed as the existing Macintosh II/IIX. The MC68030 is Motorola's second-generation 32-bit microprocessor, and combines a central processing unit, a data cache, an instruction cache, an enhanced bus controller (NOT the NuBus controller), and a memory management unit into a single VLSI device. Internal function blocks of the microprocessor are designed to operate in parallel, allowing instruction execution to overlap.

The MC68030 integrates the functionality of the MC68020 32-bit microprocessor with a subset of the MC68851 Paged Memory Management Unit (PMMU). Commonly called the 030 (pronounced "oh-three-oh"), the MC68030 is compatible with Macintosh IIX timing and software.

MC68882

The MC68882 numerics coprocessor (also called the Floating Point Unit, or FPU) provides high speed, extremely accurate, floating-point computation to IEEE standards.

The processor operates in parallel with the MC68030 and is clocked at 15.6672 MHz, using the same clock signal as the MC68030. Calls to the Apple SANE routines will use the MC68882. The MC68882, also called the 882 (pronounced "eight-eighty two"), is pin- and electrically-compatible with the MC68881 coprocessor in the Macintosh II.

Both processors use the same base instruction set--the major advantage of the MC68882 is increased speed. With the MC68882, you can perform both memory moves and chip operations in parallel--as long as they don't conflict--thus boosting floating point performance by about 15%.

Memory Management

Macintosh IICx can support the A/UX operating system without adding the PMMU, thanks to on-chip memory management by the MC68030. The MC68030 allows true 32-bit address translation with hardware page replacement. The built-in memory unit is also capable of ignoring the high 8-bits of the address to allow Macintosh software to run in 24-bit mode.

(NOTE: The MC68030 PMMU is a subset of the MC68851 PMMU, rather than an exact replacement.)

Wait States

- The Macintosh IIX/IICx uses one wait state to access the RAM.
- The Macintosh II has two wait states, one for RAM, and one for the HMMU or PMMU.

Given the CPU clock speed, you need one wait state to make sure you read from RAM at 120ns. The 15.6672 clock frequency has an active period of 63.8276ns. If the CPU reads without wait states, you would need 60ns RAM. Given the limited availability of these 60ns chips, Apple has chosen one wait state and 120ns RAM chips.

Apple SuperDrive (formerly Apple FDHD)

The Apple SuperDrive can read from and write to any of the major 3.5-inch disk formats, including Macintosh (GCR 400K, 800K, and MFM 1.44MB), Apple II (800K), MS-DOS and OS/2 (MFM 720 and 1.44MB).

GCR stands for Group Code Recording; MFM stands for Modified Frequency Modulation. MFM and GCR only effect how the bits are placed on the disk, not the directory structure. The drive is supported by the SWIM (Sander, Woz Integrated Machine) chip.

(NOTE: There is special 1.44MB media that should NOT be used in the older 400K or 800K drives.)

SWIM Chip

The SWIM chip is a single-chip combination MFM/GCR controller for internal and external floppy drives. It was designed for the SuperDrive, but is compatible with the current 400K and 800K drives. The SWIM chip replaces the IWM chip, and is pin- and function-compatible with that device.

Logic Board ROM and ROM SIMM

The Macintosh IICx comes with 256K of ROM, which is soldered to the logic board. The code in those four ROM chips is the same as the code in the IIX ROM SIMM chips. For update and upgrade purposes, the IICx logic board has a ROM SIMM slot. When the ROMs in a IICx unit are updated or upgraded, a ROM SIMM card with the new ROM chips is placed in the SIMM slot, and the jumper block on jumper W1 is removed. Removing this block disables the logic board ROM and enables the ROM SIMM.

Programmer's Switches

The programmer's switches (Reset and NMI) are located in the front of the Macintosh IICx. This allows the IICx to be placed on its side without restrictions regarding user access to the switch. This also makes it easier to move the computer off the desk to a more convenient location. As long as the user has access to the front of the computer, which is necessary to gain access to the drive port and to view the power-on and HD-activity lamps, the user can reach the programmer's switches.

Internal Hard Disk

As with the Macintosh II and IIX, the Macintosh IICx supports an internal hard disk drive. However, because the IICx has less internal space, the IICx only supports 3.5-inch mechanisms.

Functional Differences Between IICx and IIX

- NuBus Slots: Unlike the Macintosh IIX, the Macintosh IICx has three NuBus slots instead of six. The IICx NuBus slots use the exact same technology as the NuBus slots in the Macintosh II and IIX computers. As a result, the IICx NuBus slots are compatible with most of the NuBus cards that have been developed for the II and IIX. The IICx NuBus slots map to the first three NuBus slots in the II and IIX. Their slot numbers are 9, A, and B.
- Locking Power-On Switch: The power-on switch on the back of the Macintosh IICx can be locked in the on position. This feature is for IICx units that will function as routers, file servers, mail servers, etc. After power resumes after a black-out, IICx units with their power switch locked in the on position will re-boot and resume their functions.
- Power-On Signal: The power-on signal comes from the power supply on the Macintosh IICx. With the Macintosh II and IIX computers, this signal came from the logic board battery. The advantages of this feature are that the

IICx can power-up when the battery is dead, and there is less of a power drain on the battery.

- Resetting Fuses: On the Macintosh IICx logic board, there are three fuses. These fuses protect the ADB, serial, and SCSI circuitry. To reset one of these fuses after it has blown, power-down the IICx and power-up. When the unit is turned off, the blown fuse will reset. The advantage of this feature is that the logic board does not have to be replaced if a fuse is blown.

TOPIC -----

Following are the technical specifications for the Macintosh IIcx.

DISCUSSION -----

CENTRAL PROCESSING UNIT (CPU)

- Microprocessor : 15.6672 MHz MC68030 CPU
- Address Bus : 32-bit
- Registers (32-bit) : 16 general-purpose data and address, two 32-bit Supervisor stack pointers, ten special-purpose control registers
- Addressing Modes : 18
- 256-byte instruction cache and 256-byte data cache
- Built-in Paged Memory Management Unit (PMMU)

COPROCESSOR

- MC68882 floating-point unit (follows IEEE standards)

MEMORY

- 1, 2, 4, 5, 8 MB RAM (Random Access Memory)
- 256Kbytes of ROM (Read-Only Memory)
- 256 bytes of settable parameter memory with built-in battery backup

KEYBOARD (not included)

- Apple Keyboard or Apple Extended Keyboard can be connected through the Apple Desktop Bus port

MOUSE

- Apple Desktop Bus Mouse (ADB) mechanical tracking, optical shaft or contact encoding 100 +/- 10 pulses per inch (3.94 +/- 0.39 pulse per mm) of travel.

DISK DRIVE

- One 1.4 MB high-density internal Apple SuperDrive(formerly Apple FDHD).
Only one internal, floppy drive is supported. The unit ships with the Apple SuperDrive, but the logic board also supports an 800K drive.
- External connector for 800K or 1.4MB external floppy

HARD DISK DRIVE

- A 3.5" 40MB or 80MB hard drive is standard.

INTERFACES

- Two Apple Desktop Bus (ADB) connectors for keyboard, mouse, and low-speed input devices.
- Three NuBus Slots supporting full 32-bit address and data lines through a 96-pin Euro-DIN connector.
- Two RS-232/RS-422 serial ports, 230.4K baud maximum (up to 0.920 Mbit per second if clocked externally).
- SCSI interface
- Stereo sound port for external audio amplifier

SOUND GENERATION

- Apple Sound Chip (ASC) including 4-voice wave-table synthesis and stereo sampling generator capable of driving stereo mini-phono jack headphones or stereo equipment
- Mixed stereo monophonic sound output through internal speaker

ELECTRICAL REQUIREMENTS

- Line voltage: 100 to 240 volts AC, RMS automatically configured
- Line frequency: 50 to 60 hertz single phase
- Maximum power consumption: 130 watts maximum, 90 watts maximum continuous

ENVIRONMENTAL REQUIREMENTS

- Operating temperature: 50 degrees TO 104 degrees F
(10 degrees TO 40 degrees C)
- Storage temperature: -40 degrees TO 116.6 degrees F
- Relative humidity: 5% to 95% (non-condensing)
- Altitude: 0 to 10,000 ft (0 to 3048 m)
- Fan: 17 CFM radial

SAFETY AND EMI QUALIFICATIONS

- FCC part 15 Class B Computing Devices
- UL 478 Electronic Data Processing Equipment
- CSA (Canadian Standards Assn.) 220 Information Processing and Business Equipment

SIZE AND WEIGHT

- Main Unit
 - Height: 5.5 inches (140 mm)
 - Width: 11.9 inches (302 mm)
 - Depth: 14.4 inches (365 mm)
 - Weight: 13 lbs. 10 oz. (6.2 kg)
- Apple Keyboard (not included)
 - Height: 1.8 inches (44.5 mm)

Width: 16.5 inches (418.3 mm)

Depth: 5.6 inches (142.0 mm)

Weight: 2 lbs. 2 oz. (1 kg)

- Apple Extended Keyboard (not included)

Height: 2.3 inches (56.4 mm)

Width: 19.1 inches (486 mm)

Depth: 7.4 inches (188 mm)

Weight: 3 lbs. 10 oz. (1.6 kg)

- Apple Mouse (ADB)

Height: 1.1 inches (27.9 mm)

Width: 2.1 inches (53.3 mm)

Depth: 3.8 inches (96.5 mm)

Weight: 6 oz. (.175 kg)

5.25-Inch 160MB SCSI Hard Disk Drive

Revised: 4/11/91
Security: Everyone

5.25-Inch 160MB SCSI Hard Disk Drive

=====

Apple has announced a 5.25-inch 160MB SCSI hard disk drive. The internal configuration is optional in the Macintosh II and Macintosh IIX. In addition, upgrade kits will be available for these systems.

This 160MB SCSI hard disk drive has been tested to support the Macintosh OS and A/UX. However, this drive can not be used with the Apple II family.

Like other 5.25-inch drives, this drive does not fit in the Macintosh IICx or the compact Macintosh systems. However, as an external drive, it works with any Macintosh that has a SCSI port.

Technical specifications:

Capacity

Formatted data capacity:	160MB
Data surfaces:	5
Heads per surface:	1
Block size:	512 bytes
Total disk blocks:	327,780

Characteristics

Average seek time:	18 milliseconds
Transfer rate:	up to 1.25MB/sec
Rotation speed:	3,600 RPM
Startup:	20 seconds
Spindown:	20 seconds

Physical

Form Factor:	5.25-inch, half height
Weight:	2.09 kg (4.6 lbs) - internal configuration

Macintosh II: Monochrome Video Card

Revised: 3/9/89
Security: Everyone

Macintosh II: Monochrome Video Card

=====

Apple has announced the Macintosh II Monochrome Video card. It is a one bit per pixel (two gray levels) NuBus video card. It is positioned as a low-cost monochrome video card.

This card was designed to be used with the High-Resolution Monochrome Monitor. It also works with the AppleColor High-Resolution RGB Monitor, but this use is not being promoted. This card is not compatible with the Macintosh II Two-Page Monochrome or Portrait Display monitor.

The pixel display RAM capacity cannot be upgraded on this card.

Technical specifications:

Display Resolution:	640 pixel horizontally by 480 pixel vertically
Connector:	15 pin D-style
Display Mode:	1 bit per pixel only
Output Signal:	RS-343 standard with composite synchronization on the negative going TTL
Raster Rates:	Vertical - 66.7 hertz Horizontal - 35.0 kilohertz Dot Clock - 30.24 megahertz
Power Consumption:	5 watts

LaserWriter: 1000-Sheet Paper Bin

Revised: 3/9/89
Security: Everyone

LaserWriter: 1000-Sheet Paper Bin

=====

This article last reviewed: 8 March 1989

Laser Connection offers a motorized paper tray that can hold up to 1000 sheets of paper stock. This product, named the Big Bin, eliminates the need to continually reload the standard LaserWriter paper cassette, which holds only about 100 sheets of paper. For more details, search the Tech Info Library under "Laser Connection".

Macintosh II: Portrait Display Monitor: Its ADB Ports

Revised: 3/9/89
Security: Everyone

Macintosh II: Portrait Display Monitor: Its ADB Ports

=====

This article last reviewed: 8 March 1989

The Macintosh II Portrait Display Monitor has three Apple Desktop Bus (ADB) ports built into the monitor.

The Macintosh II Portrait Display Monitor has three ADB ports built into the back panel of the monitor. This makes it easier for the user to configure the Macintosh in a way that fits a user's workspace.

Why three ports when the Macintosh II has only two? Only two of the ports are usable, because the third must be used to connect the monitor to an ADB port on the Macintosh. Thus, one ADB cable runs from the Macintosh to the monitor, activating the other two monitor ADB ports.

Multiple Monitor Incompatibilities With Software

Revised: 3/9/89
Security: Everyone

Multiple Monitor Incompatibilities With Software

=====

This article last reviewed: 8 March 1989

This article describes applications that exhibit poor behavior on multiple monitors.

4th Dimension 1.0.6

Windows does not move to other monitors, when the in user or custom mode.

Illustrator 88 v1.6

Illustrator crashes on launch with any video card. This has been corrected in v1.7.

Cricket Draw 1.1.1

If a document is opened, moved onto another monitor, saved, and then the Monitor's CDEV is reconfigured, the document may become inaccessible. Original configuration must be restored to access document.

Cricket Presents 1.0

The program mistakenly identifies the Macintosh IIcx and Macintosh IIX as Macintosh Plus, and thus limits the user to only the eight, basic QuickDraw colors.

FullWrite 1.0

If more than one video card is installed, FullWrite places the spell check dialog on the second monitor. If no monitor is attached to the card, this prevents the dialog from appearing at ll.

Graphist Paint II 1.0

This application does not open on 030 Macs. Unlikely to be updated, as Aba

Software has filed for bankruptcy.

Pixel Paint 1.1

Pixel Paint only works with a color monitor, and does not work on multiple monitors. Tools do not work anywhere, but on the primary monitor.

SuperPaint 1.1

SuperPaint does not support more than 1-bit (black and white) or multiple monitors.

Swivel 3D 1.0

Swivel effect will not occur on secondary monitors. The change will not occur until after the mouse button is released.

Conclusion

It should also be noted that Apple, by providing a multi-monitor environment, has expanded the types of configurations applications must recognize.

Also, some applications exhibit different "Zoom Box" behaviors than is usual in a multi-monitor set up. This does not cause any functionality problems, but some behaviors appropriate on a single monitor may not be appropriate on multiple monitors (for example, which monitor the zoom out window appears on).

Apple Two-page Monochrome Monitor: Images Vibrate

Revised: 3/9/89
Security: Everyone

Apple Two-page Monochrome Monitor: Images Vibrate

=====

This article last reviewed: 8 March 1989

Interference between two monitors placed side-by-side can cause images on the monitors to vibrate. The reason is that, when placed side-by-side, monitors can magnetically interfere with each other, causing the image on one or both monitors to appear to vibrate slightly. This interference problem is most often seen when an RGB color monitor is placed next to a large-screen monochrome monitor. The amount of interference can also vary depending on the user's environment.

Moving the monitors further apart, especially the rear ends, usually reduces the vibration effect.

Technical Reason For Picture Vibrating

The cause of this shimmering effect lies in the vertical refresh rate, the number of times a monitor repaints the screen each second. When this rate differs significantly between monitors, the interference described above can occur. There is often a large difference between RGB and monochrome monitors. Thus, the vibration effect most often occurs with this combination. Because other factors are involved, it is possible for two monitors with the same refresh rate to exhibit this effect, although this is less frequent.

Shielding monitors so as to prevent this type of interference would add a great deal to the cost of each monitor. Further, by shielding a monitor you can prevent the monitor from interfering with other monitors, but other monitors could still interfere with it. Apple is investigating a number of technologies to prevent this interference in the future and plans to incorporate them as they become feasible.

Apple Two-Page Monochrome Monitor: Image Tilt

Revised: 3/9/89
Security: Everyone

Apple Two-Page Monochrome Monitor: Image "Tilt"

=====

This article last reviewed: 8 March 1989

Magnetic fields can cause the image to "tilt" on the Apple Two-Page Monochrome Monitor.

Occasionally, the monitors exhibit a tilt in the screen image, either to the right or left. The tilt is only noticeable, if you look at the edges of the screen and notice the amount of black space around the image. Sometimes the amount of black space is greater or less than the amount on the opposite end of the screen. Image quality is not affected. Larger monitors, like the Apple Two-Page Monochrome Monitor, are more likely to show the effect than small monitors.

If a monitor exhibits this effect, say a tilt down to the right, rotating the monitor around on its swivel base by 180 degrees will cause the image to tilt up to the right. What this means is that by rotating the monitor about 90 degrees in either direction, causes the effect to disappear with no tilt present. It also occurs in varying degrees, depending on location. This does not occur with every monitor.

Technical Reason For The Tilt

This effect is caused by differences in the magnetic fields in different places, usually where there is a strong magnetic field being caused by power generators or wiring. A monitor, when set up in one place, may exhibit no tilt, but, when placed somewhere else, may show the above effect. To remove all possible outside influence, Apple tests for true image distortion within large magnetic coils that are designed to simulate normal magnetic fields (when such fields are present). Thus, when shipped, monitors are perfectly aligned, and any distortion is related to the environment into which the monitor is placed.

Why does this occur on the Two-Page display and not on other monitors or on televisions? There are two reasons for this. First, to improve image

quality and lessen eye strain, Apple attempts to make its displays as flat as possible. Thus the picture tube is physically flatter than most every tube on the market today. This presents less image distortion (like bowing of straight lines) and makes the screen image look more like a single sheet of paper. However, the tilt effect tends to be more noticeable on large flat tubes. Competitive, large-screen monitors also show this effect.

The reason televisions do not exhibit this characteristic is that they "overscan" the screen, using all of the picture tube, thus no black space is visible on the edges of the screen. Thus, any tilt to the image is hidden from view. The tilt is there, it just cannot be seen. Macintosh computer displays cannot use this technique, because all information on the screen is critical and cannot flow off the screen (like the menu bar).

Apple Two-Page Monochrome Monitor: Specs (Discontinued)

Revised: 9/13/93
Security: Everyone

Apple Two-Page Monochrome Monitor: Specs (Discontinued)

Article Created: 9 March 1989
This article last reviewed: 8 March 1989

This article gives the specifications for the Apple Two-Page Monochrome Monitor along with Pin assignments for input signal jack.

Picture Tube	21-inch diagonal Phosphor EIA Type P4 (White) High-contrast antiglare
Input Signal	Video: RS-343 standard Sync: Separate sync, negative going, TTL
User Controls	Power Switch (back panel) Brightness, with detent reference (right side) Contrast (right side)
Scanning Frequencies	Horizontal 68.7 kHz Vertical 75.0 Hz
Resolution	1152 (H) dots by 870 (V) lines
Active Video Display Area	Adjusted at the factory to produce an active video area of 15-inch horizontal by 11.33-inch vertical. The remainder of the screen is used for the dark border around the display.
Weight	60 lbs, approximately
Power Requirements	100 watts maximum, all line conditions
Input Voltage	Operating range 90-270 Vrms, self-configuring Frequency 47-63 Hz

Operating Ambient Temperature	10 degrees C to 35 degrees C (50 degrees F to 95 degrees F)
Operating Humidity	90% maximum, non-condensing
Operating Altitude	10,000 feet maximum
Fuse Protection	The monitor contains internal power line fuse protection. This fuse should be replaced with the same type be a qualified service technician.
Warm-up Time	20 minutes to meet all specifications

Pin Assignments For Input Signal Jack (D-25 Shell Style)

Pin	Function
A1	Monochrome video
A2	75 Ohms #1
A3	75 Ohms #2
1	Hsync return
2	Vsync
3	Sense #3
4	Sense return
5	Csync
6	Hsync
7	Vsync return
8	Sense #2
9	Sense #1
10	Csync return
Shell	Shell ground

AppleShare: Problem Launching Applications (10/93)

Revised: 10/26/93
Security: Everyone

AppleShare: Problem Launching Applications (10/93)

=====

Article Created: 20 January 1989
Article Reviewed/Updated: 25 October 1993

TOPIC -----

Using AppleShare, if you double click on the local documents of applications that are known to be on a mounted AppleShare volume, you may get a message that the application is missing or busy. How do I fix it so that double clicking will open the document?

DISCUSSION -----

Under AppleShare 3.0.x

Most likely, the desktop files on the file server need to be rebuilt. The most effective way of rebuilding the server desktop is to restart the server with the shift key depressed until the "Extensions Disabled" message appears in the Welcome to Macintosh window. Then depress the COMMAND and OPTION simultaneously until the "Are you sure you want to rebuild the desktop..." message appears. (This message will appear for each volume.) Click OK to start the rebuild. This process will ensure a complete desktop rebuild.

Under AppleShare 2.0.x

Most likely, the problem is not with the Desktop file for the hard drive but with the Server Desktop files (Desktop DB and Desktop DF), which are invisible and located in the Server Folder.

Rebuilding the desktop files of an AppleShare Server volume is a little tricky. You need to restart the AppleShare Server from a floppy (or a non AppleShare Server volume). If you restart the AppleShare Server from a floppy and rebuild the desktop as described above, you are only rebuilding the standard desktop file on that volume, not the AppleShare Server "desktop files" (Desktop DB and Desktop DF). If, however, you restart the server with the Server Administration disk or any other floppy disk with

the Desktop Manager in its System Folder, the Desktop Manager becomes active, and the AppleShare "desktop file" can be rebuilt.

The standard desktop file is different from the AppleShare "desktop file". The AppleShare "desktop file" consists of two files, Desktop DB and Desktop DF, that serve the same purpose for multiple users under AppleShare as the standard desktop file does for a single-user Macintosh. The Desktop DB and Desktop DF files are used only if the Desktop Manager is active, as in the case of an AppleShare server. Then the standard desktop file is not used.

Apple HD SC Setup 2.0 Update Not Backward Compatible

Revised: 4/11/91
Security: Everyone

Apple HD SC Setup 2.0 Update Not Backward Compatible

=====

This article last reviewed: 20 January 1989

Apple HD SC Setup 2.0 is able to update the drivers only on hard drives formatted with HD SC Setup 2.0.

For example, if a hard disk was formatted with HD SC Setup 1.5 or earlier, HD SC Setup 2.0 will NOT be able to update the drivers on that drive. Apple HD SC Setup 2.0 is completely compatible with System Software 6.0.2.

It's okay to use versions of HD SC Setup older than version 2.0 with System Software 6.0.2, but we recommend using the latest version of HD SC Setup whenever possible.

Macintosh SE Memory Upgrade: Questions And Answers (11/95)

=====

Article Created: 21 January 1989
Article Reviewed/Updated: 29 November 1995

TOPIC -----

Some questions and answers about Macintosh SE memory upgrades. Note that some of these memory kits are no longer available.

DISCUSSION -----

Question: Will the M0707 memory kit work in a Macintosh SE?

Answer: No. There is not enough room in the Macintosh SE's chassis to accommodate the larger chips.

Question: What kit does Apple recommend for upgrading those machines?

Answer: The standard 2MB memory upgrade was the only Apple solution available for the Macintosh SE. Third-party memory solutions are also available.

Question: Has the Macintosh SE frame been changed to support the larger DIP SIMMs (M0707)?

Answer: No, the Macintosh SE frame has not been changed to accommodate the larger DIP SIMMs.

Question: Is Apple still using the 150ns 256K SIMM chips in the M0218?

Answer: The 1MB upgrade with the 256 kilobit chips used 120ns chips. This was necessary for the chips to be able to work in the Macintosh II. This upgrade was also used to expand a 1MB Macintosh II to 2MB, and the Macintosh II requires 120ns chips.

NOTE:

The 150ns 256 kilobit chips were only an issue when they were removed from a Macintosh SE that is upgraded using the 2MB upgrade. If these chips were then used in a Macintosh II, memory errors occurred.

AppleShare Memory Problem: Solved For System 4.2 And MultiFinder

=====

This article last reviewed: 21 January 1989

Using System 4.2 and Finder 6.0, you may find that when using the AppleShare workstation software you get the error message "There isn't enough memory to work with CS Server 20" at startup.

You probably need to increase the MultiFinder partition for the Finder.

To do this, select the Finder icon and choose "Get Info" from the File menu in the Finder. Set the Finder's partition to something other than the default value of 160K (somewhere around 320K should do it).

The partition generally needs to be increased to deal with many open windows, large DeskTop files, and large directories.

Star Micronics Delta 15 Printer: Printing From Apple IIe

=====

This article last reviewed: 26 January 1989

To print from an Apple IIe to a Star Micronics Delta 15 printer at 2400 baud, XON-XOFF handshake, 8-bit data, and 1 stop bit, the switches should be set as follows:

Super Serial Card	
(configuration block set to printer)	
Sw-1	Sw-2
1 OPEN	CLOSED
2 CLOSED	CLOSED
3 OPEN	CLOSED for 80 col., OPEN for 132 col.
4 CLOSED	OPEN
5 OPEN	CLOSED for auto LF, OPEN for no LF
6 CLOSED	OPEN
7 CLOSED	OPEN

Delta 15 Printer	
Sw-2	Sw-3
1 na	OPEN
2 CLOSED	OPEN
3 na	CLOSED
4 na	CLOSED
5 na	na
6 na	CLOSED
7 na	OPEN
8 na	CLOSED

The cable connecting the SSC and printer should be wired as follows:

SSC	Printer
1	1
2	3
3	2
4	- tie directly to pin 5

5	-	no connection on printer end
7		7
8		not used
19		not used
6	-	tie directly to pin 20
20	-	no connection on printer end

Macintosh System Software: Configuring For Different Models

Revised: 4/11/91
Security: Everyone

Macintosh System Software: Configuring For Different Models

=====

This article last reviewed: 21 January 1989

When supporting very large numbers of Macintosh users using different Macintosh models, it may be important to keep the number of variations in system loads to a minimum. Therefore, it may be advantageous to use common system software for all the different Macintoshes.

If you are going to choose common system software for Macintosh Plus, Macintosh SE, and Macintosh II/Macintosh IIX systems, it is best to install the current system for Macintosh II/Macintosh IIX. This ensures that all CDEVs usable by the Macintosh Plus, Macintosh SE, and Macintosh II/Macintosh IIX systems are available.

The patches for the Macintosh Plus, Macintosh SE, and Macintosh II/Macintosh IIX systems are present regardless of the Macintosh model in which the system software was installed, and are loaded only as needed.

For example, the Macintosh SE patches are loaded by the system when a Macintosh SE is used; the Macintosh Plus and Macintosh II/Macintosh IIX patches are not loaded.

The only penalty for use of the Macintosh II/IIX system will be a slight increase in the amount of disk space used. Performance will not be affected.

ImageWriter II: Line Feed Peculiarity

Revised: 4/11/91
Security: Everyone

ImageWriter II: Line Feed Peculiarity

=====

This article last reviewed: 18 January 1989

Using the ImageWriter II, you may experience the following problem:

- The ImageWriter II appears to treat a single line-feed character (\$0A) in the middle of a character string as a line feed/carriage return combination.
- A line feed at the beginning of a line (that is, immediately following a carriage return) seems to behave normally, but if the line feed is in the middle of a line, the printer starts any text that occurs after that character on the next printed line at column 1.

The ImageWriter II Technical Reference Manual (ISBN #0-201-17739-0), Chapter 5: Page Formatting, page 75, says:

"When you turn on the ImageWriter II, it's set to print out the data in the print buffer and to insert a carriage return (CR) before every line feed (LF) or form feed (FF) character it receives."

The user can control whether a CR is inserted before each LF or FF by sending specific codes to disable this function. To disable the CR insertion, send an Esc l (lower case L) 1 (one). To enable CR insertion before LF and FF, send Esc l (lower case L) 0 (zero).

Sending the Esc l 1 will suppress the CR after LF and permit the type of printing you wish. (See the example of on page 76 in the same manual.)

SIMMs: Some Are For 68030-Based Systems Only

Revised: 5/27/92
Security: Everyone

SIMMs: Some Are For 68030-Based Systems Only

=====

Article created: 2 March 1989
Article last reviewed: 20 May 1992
Article last updated:

Some of the SIMMs that are used in the Macintosh IIX will not work in other systems (Macintosh II, Macintosh SE, etc). They have "030 ONLY" stamped on the back.

They don't work in other Macintosh systems because the CAS/RAS signals are reversed (timing-related) from previous SIMMs.

This difference is handled in the Macintosh IIX with additional ROM code. Those SIMMs that are marked for "030 ONLY" will work only in the Macintosh IIX (and any future machines that use the 68030 processor).
